

MODULI SCHEMES
OF GENERICALLY SIMPLE AZUMAYA MODULES

Communicated by Ulf Rehmann

ABSTRACT. Let A be an Azumaya algebra over a smooth projective variety X or more generally, a torsion free coherent sheaf of algebras over X whose generic fiber is a central simple algebra. We show that generically simple torsion free A -module sheaves have a projective coarse moduli scheme; it is smooth and even symplectic if X is an abelian or K3 surface and A is Azumaya. We explain a relation to the classical theory of the Brandt groupoid.

Keywords and Phrases: Moduli space, torsion free sheaf, Azumaya module, Brandt groupoid

INTRODUCTION

Let X be a smooth projective variety, e.g. a surface, over an algebraically closed field k . Let \mathcal{A} be a sheaf of Azumaya algebras over X or more generally, a torsion free coherent sheaf of algebras over X whose generic fiber \mathcal{A}_η is a central simple algebra over the function field of X . This paper is about moduli schemes of generically simple, locally projective \mathcal{A} -module sheaves E .

These moduli schemes are in close analogy to the Picard variety of X . In fact, our main result says that we do not need any stability condition for our sheaves E to construct coarse moduli schemes parameterizing them, say with fixed Hilbert polynomial or Chern classes. We find that these schemes are in general not proper over k , but they have natural compactifications: Working with torsion free sheaves E instead of only locally projective ones, we obtain projective moduli schemes.

This gives lots of interesting moduli spaces, which certainly deserve further study. For example, we show in section 3 that they are smooth projective and even symplectic if X is an abelian or K3 surface and \mathcal{A} is an Azumaya algebra. They are also related to classifying isomorphism types of Azumaya algebras

\mathcal{A} in a given central division algebra $\mathcal{A}_\eta = D$, a topic already present in the classical literature on algebras; this relation is explained in section 4.

We construct these moduli schemes in section 2. We use standard techniques from geometric invariant theory (GIT) and a boundedness result, which has been known for some time in the case of characteristic $\text{char}(k) = 0$, but is one of the deep results of A. Langer in [9] for $\text{char}(k) = p > 0$. Our construction works for any integral projective scheme X over k ; the precise setup is formulated in section 1. As M. Lieblich has pointed out to us, this construction can also be seen as a special case of Simpson's general result [16, Theorem 4.7], at least if $\text{char}(k) = 0$; for $\text{char}(k) = p > 0$ see also [10].

In section 3, we apply deformation theory to our \mathcal{A} -modules, mainly in the case where X is a surface and \mathcal{A} is an Azumaya algebra. Besides the smoothness mentioned above, we also show here that torsion free sheaves are really necessary to obtain projective moduli schemes, because locally projective sheaves of \mathcal{A} -modules can degenerate to torsion free ones.

During the final preparations of this paper, we were informed about the MIT-thesis of M. Lieblich [13, 12]. This thesis works much more systematically and abstractly and contains several results similar to ours in the language of algebraic stacks. We thank A. J. de Jong and M. Lieblich for informations concerning their work. Similar results have also been obtained independently by K. Yoshioka [17]; they have been used by D. Huybrechts and P. Stellari [8] to prove a conjecture of Caldararu. We thank F. Heinloth, J. Heinloth, Y. Holla and A. Langer for useful comments and discussions.

1 FAMILIES OF \mathcal{A} -MODULES

Let X be an integral projective scheme over the algebraically closed field k . Throughout this paper, \mathcal{A} denotes a sheaf of associative \mathcal{O}_X -algebras satisfying the following properties:

1. As a sheaf of \mathcal{O}_X -modules, \mathcal{A} is coherent and torsion free.
2. The stalk \mathcal{A}_η of \mathcal{A} over the generic point $\eta \in X$ is a central simple algebra over the function field $F = k(X) = \mathcal{O}_{X,\eta}$.

For example, X could be a smooth projective variety over k , and \mathcal{A} could be a sheaf of Azumaya algebras over X .

REMARK 1.1. If $\dim X = 1$, then \mathcal{A}_η is a matrix algebra over $k(X)$ by Tsen's theorem. So the first interesting case is $\dim X = 2$.

Our main objects will be generically simple torsion free \mathcal{A} -modules, i. e. sheaves E of left \mathcal{A} -modules over X which are torsion free and coherent as \mathcal{O}_X -modules and whose generic fiber E_η is a simple module over the central simple algebra \mathcal{A}_η . By Wedderburn's structure theorem, we have $\mathcal{A}_\eta \cong \text{Mat}(n \times n; D)$ for a division algebra D , say of dimension r^2 over $k(X)$; that E_η is simple means that

it is Morita equivalent to a one-dimensional vector space over D . In particular, E has rank r^2n over \mathcal{O}_X .

Note that any such \mathcal{A} -module E has only scalar endomorphisms: Indeed, $\text{End}_{\mathcal{A}}(E)$ is a finite-dimensional k -algebra; it has no zero-divisors because it embeds into the division algebra $\text{End}_{\mathcal{A}_\eta}(E_\eta) \cong D^{\text{op}}$. This implies $\text{End}_{\mathcal{A}}(E) = k$ because k is algebraically closed.

LEMMA 1.2. *Suppose that $k \subseteq K$ is a field extension, and let $K(X_K)$ be the function field of $X_K := X \times_k \text{Spec } K$. If D is a finite-dimensional division algebra over $k(X)$, then $D_K := D \otimes_{k(X)} K(X_K)$ is a division algebra, too.*

Proof. Since k is algebraically closed, $k(X) \otimes_k K$ is an integral domain; its quotient field is $K(X_K)$. Suppose that D_K contains zero divisors. Clearing denominators, we can then construct zero divisors in $D \otimes_{k(X)} (k(X) \otimes_k K)$, which is clearly isomorphic to $D \otimes_k K$. Consequently, there is a finitely generated k -algebra $A \subseteq K$ such that $D \otimes_k A$ contains zero divisors. These zero divisors are automatically nonzero modulo some maximal ideal $\mathfrak{m} \subset A$, so $D \otimes_k A/\mathfrak{m}$ also contains zero divisors. But $A/\mathfrak{m} \cong k$ by Hilbert’s Nullstellensatz; hence D contains zero divisors. This contradiction shows that D_K has to be a division algebra if D is. □

COROLLARY 1.3. *If E is a generically simple torsion free \mathcal{A} -module, then the pullback E_K of E to X_K is a generically simple torsion free module under the pullback \mathcal{A}_K of \mathcal{A} .*

Proof. E_K is clearly torsion free and coherent over \mathcal{O}_{X_K} . Since the generic fiber of E is Morita equivalent to a one-dimensional D -vector space, the generic fiber of E_K is Morita equivalent to a one-dimensional D_K -vector space; hence E_K is generically simple. □

DEFINITION 1.4. *A family of generically simple torsion free \mathcal{A} -modules over a k -scheme S is a sheaf \mathcal{E} of left modules under the pullback \mathcal{A}_S of \mathcal{A} to $X \times_k S$ with the following properties:*

1. \mathcal{E} is coherent over $\mathcal{O}_{X \times_k S}$ and flat over S .
2. For every point $s \in S$, the fiber \mathcal{E}_s is a generically simple torsion free $\mathcal{A}_{k(s)}$ -module.

Here $k(s)$ is the residue field of S at s , and the fiber \mathcal{E}_s is by definition the pullback of \mathcal{E} to $X \times_k \text{Spec } k(s)$.

We denote the corresponding moduli functor by

$$\mathcal{M} = \mathcal{M}_{\mathcal{A}/X} : \underline{Sch}_k \longrightarrow \underline{Sets};$$

it sends a k -scheme S to the set of isomorphism classes of families \mathcal{E} of generically simple torsion free \mathcal{A} -modules over S . Our main goal is to construct and study coarse moduli schemes for this functor.

If \mathcal{E} is a family of generically simple torsion free \mathcal{A} -modules over S , then there is an open subset of S above which these \mathcal{A} -modules are locally projective. However, we work with all torsion free \mathcal{A} -modules because they satisfy the following valuative criterion for properness:

PROPOSITION 1.5. *Let V be a discrete valuation ring over k with quotient field K . Then the restriction map*

$$\mathcal{M}(\mathrm{Spec} V) \longrightarrow \mathcal{M}(\mathrm{Spec} K)$$

is bijective.

Proof. Let $\pi \in V$ be a uniformising element, and let $l = V/(\pi)$ be the residue field of V . We denote by

$$X_K \xrightarrow{j} X_V \xleftarrow{i} X_l$$

the open embedding of the generic fiber and the closed embedding of the special fiber; here $X_A := X \times_k \mathrm{Spec} A$ for any k -algebra A . Let η (resp. ξ) be the generic point of X_K (resp. of X_l), and let

$$j_\eta : \mathrm{Spec} \mathcal{O}_{X_V, \eta} \longrightarrow X_V \quad (\text{resp. } j_\xi : \mathrm{Spec} \mathcal{O}_{X_V, \xi} \longrightarrow X_V)$$

be the ‘inclusion’ morphism of the subset $\{\eta\}$ (resp. $\{\xi, \eta\}$) into X_V . Let $E \in \mathcal{M}(\mathrm{Spec} K)$ be an \mathcal{A}_K -module.

Assume given an extension $\mathcal{E} \in \mathcal{M}(\mathrm{Spec} V)$ of E . Then \mathcal{E} embeds canonically into j_*E ; in particular, the stalk \mathcal{E}_ξ over the discrete valuation ring $\mathcal{O}_{X_V, \xi}$ embeds into the generic fiber E_η . \mathcal{E} is uniquely determined by E and \mathcal{E}_ξ because

$$\mathcal{E} = j_*E \cap j_{\xi,*}\mathcal{E}_\xi \subseteq j_{\eta,*}E_\eta; \tag{1}$$

this equation follows easily from the assumption that the special fiber $i^*\mathcal{E}$ is torsion free, cf. the proof of [11, Proposition 6].

Moreover, the \mathcal{A} -stable $\mathcal{O}_{X_V, \xi}$ -lattice $\mathcal{E}_\xi \subset E_\eta$ is unique up to powers of π because its quotient modulo π is a simple module under the generic fiber of \mathcal{A}_l by corollary 1.3. This implies that \mathcal{E} is determined by E up to isomorphism, thereby proving injectivity.

To prove surjectivity, we construct an extension \mathcal{E} of E as follows: The simple \mathcal{A}_η -module E_η is Morita equivalent to a one-dimensional vector space over the division algebra $D_K = D \otimes_{k(X)} \mathcal{O}_{X_V, \eta}$. Inside this vector space, we choose a free module of rank one over $D_V := D \otimes_{k(X)} \mathcal{O}_{X_V, \xi}$ and denote by \mathcal{E}_ξ the Morita equivalent submodule of E_η . Then we define \mathcal{E} by (1); this clearly defines a sheaf of \mathcal{A}_V -modules over X_V which is flat over V , whose generic fiber $j^*\mathcal{E}$ is E , and whose special fiber $i^*\mathcal{E}$ is generically simple. According to the proof of [11, Proposition 6] again, \mathcal{E} is coherent over \mathcal{O}_{X_V} , and its special fiber $i^*\mathcal{E}$ is torsion free. This shows $\mathcal{E} \in \mathcal{M}(\mathrm{Spec} V)$. \square

REMARK 1.6. Suppose that X is smooth. In the trivial case $\mathcal{A} = \mathcal{O}_X$, generically simple locally projective \mathcal{A} -modules are just line bundles, so they also satisfy the valuative criterion for properness; here locally projective and only torsion free modules lie in different connected components of the moduli space. This is no longer true for nontrivial \mathcal{A} , even if \mathcal{A} is a sheaf of Azumaya algebras over an abelian or K3 surface X : If \mathcal{A}_η is not just a full matrix algebra over $k(X)$, then every generically simple torsion free \mathcal{A} -module is a degeneration of locally projective ones by theorem 3.6.iii below; in particular, the latter do not satisfy the valuative criterion for properness.

2 CONSTRUCTION OF THE COARSE MODULI SCHEMES

We choose an ample line bundle $\mathcal{O}_X(1)$ on X and put $d := \dim(X)$. As usual, the Hilbert polynomial $P(E)$ of a coherent sheaf E on X with respect to this choice is given by

$$P(E; m) := \chi(E(m)) = \sum_{i=0}^d (-1)^i \dim_k H^i(X; E(m))$$

where $E(m) := E \otimes \mathcal{O}_X(1)^{\otimes m}$. See [7, Chapter 1.2] for details about $P(E)$, in particular for the fact that it is a polynomial of degree $d = \dim(X)$ if E is torsion free.

Recall that the Hilbert polynomial is locally constant in flat families. Keeping it fixed, we denote by

$$\mathcal{M}_{\mathcal{A}/X;P} : \underline{Sch}_k \longrightarrow \underline{Sets}$$

the subfunctor of $\mathcal{M}_{\mathcal{A}/X}$ that parameterizes families \mathcal{E} all of whose fibers \mathcal{E}_s have Hilbert polynomial P .

Our first aim is to prove that the class $\mathcal{M}_{\mathcal{A}/X;P}(\text{Spec } k)$ of generically simple torsion free \mathcal{A} -modules E with Hilbert polynomial P is bounded (in the sense of [7, Definition 1.7.5]); this will follow easily from the following apparently weaker statement:

PROPOSITION 2.1. *The class of coherent \mathcal{O}_X -modules E with the following two properties is bounded:*

1. *E is torsion free and has Hilbert polynomial P .*
2. *E admits at least one \mathcal{A} -module structure for which it is generically simple.*

Proof. Suppose that E is such a sheaf on X . We recall a few concepts, which are all in [7, Chapter 1.2].

$$\text{rk}(E) := \dim_F(E_\eta), \quad \text{deg}(E) := c_1(E) \cdot \mathcal{O}_X(1)^{d-1}, \quad \mu(E) := \frac{\text{deg}(E)}{\text{rk}(E)}$$

denote the rank, degree and slope of E . Writing the Hilbert polynomial as

$$P(E; m) = \sum_{i=0}^d \alpha_i(E) \binom{m+i-1}{i}$$

with integral coefficients α_i [7, Chapter 1.2], one has

$$\deg(E) = \alpha_{d-1}(E) - \operatorname{rk}(E)\alpha_{d-1}(\mathcal{O}_X),$$

cf. [7, Definition 1.2.11]. As $P(E)$ is fixed, it follows in particular that the slope $\mu(E) = \mu$ is fixed. We denote

$$\mu_{\max}(E) := \max\{\mu(E') \mid 0 \neq E' \subseteq E \text{ a coherent } \mathcal{O}_X\text{-subsheaf of } E\}.$$

$\mu_{\max}(E)$ is in fact the slope of the first subsheaf $E_{\max} \subseteq E$ in the μ -Harder-Narasimhan filtration of E [7, Section 1.6].

According to a deep result of A. Langer [9, Theorem 4.2], our class of \mathcal{O}_X -modules E is bounded if the numbers $\mu_{\max}(E)$ are bounded from above. To check the latter, we choose an integer $m \in \mathbb{Z}$ such that the coherent sheaf $\mathcal{A}(m)$ is generated by its global sections. Since E is generically simple, the multiplication map

$$\mathcal{A} \otimes_{\mathcal{O}_X} E_{\max} \longrightarrow E$$

is generically surjective. Consequently, the induced map

$$H^0(\mathcal{A}(m)) \otimes_k E_{\max} \longrightarrow E(m)$$

is generically surjective, too. But E certainly has a μ -semistable torsion free quotient E'' with $\mu(E'') \leq \mu$, e.g. the last quotient from the μ -Harder-Narasimhan filtration of E . It is easy to see that there is a nonzero map $E_{\max} \rightarrow E''(m)$, obtained by composing

$$E_{\max} \longrightarrow E(m) \longrightarrow E''(m).$$

Since E_{\max} and $E''(m)$ are μ -semistable, this implies

$$\mu_{\max}(E) = \mu(E_{\max}) \leq \mu(E''(m)) = m\mu(\mathcal{O}_X(1)) + \mu(E'') \leq m\mu(\mathcal{O}_X(1)) + \mu.$$

This is the required bound for $\mu_{\max}(E)$. □

According to the proposition, there is an integer $m = m_{\mathcal{A}/X;P}$ with the following property: For every generically simple torsion free \mathcal{A} -module E with Hilbert polynomial P , $E(m)$ is generated by global sections, and $H^i(E(m)) = 0$ for all $i > 0$. We keep this m fixed in the sequel and denote by $N := P(m)$ the common dimension of all the vector spaces $H^0(E(m))$.

PROPOSITION 2.2. *i) There is a fine moduli scheme R of finite type over k that parameterizes generically simple torsion free \mathcal{A} -modules E with Hilbert polynomial P together with a basis of $H^0(E(m))$.*

- ii) For $l \gg m$, there is an ample line bundle L_l on R whose fibre at E is canonically isomorphic to $\det H^0(E(l))$.
- iii) The algebraic group $GL(N)$ over k acts on R by changing the chosen bases of the $H^0(E(m))$.
- iv) There is a natural action of $GL(N)$ on L_l that lifts the action in iii.
- v) The scheme-theoretic stabilizer of every point in $R(k)$ coincides with the scalars $\mathbb{G}_m \subseteq GL(N)$.

Proof. i) Let $\text{Quot}_P(\mathcal{A}(-m)^N)$ be Grothendieck's Quot-scheme parameterizing coherent quotients E with Hilbert polynomial P of the \mathcal{O}_X -module sheaf $\mathcal{A}(-m)^N$. We can take for R the locally closed subscheme of $\text{Quot}_P(\mathcal{A}(-m)^N)$ defined by the following conditions:

1. The quotient sheaf E is torsion free.
2. E is an \mathcal{A} -module, i. e. the kernel of $\mathcal{A}(-m)^N \rightarrow E$ is an \mathcal{A} -submodule.
3. As an \mathcal{A} -module, E is generically simple.
4. The following composed map is an isomorphism:

$$k^N \longrightarrow H^0(\mathcal{A}^N) \longrightarrow H^0(E(m)).$$

Here the left map is given by the unit of the algebra \mathcal{A} .

(In particular, this proves that the class of \mathcal{A} -modules E in question is bounded.)

ii) By Grothendieck's construction of Quot-schemes, the L_l are a fortiori ample line bundles on $\text{Quot}_P(\mathcal{A}(-m)^N)$.

iii) and iv) also hold for the whole Quot-scheme, cf. [7, 4.3], and its subscheme R is clearly $GL(N)$ -invariant.

v) Let E be a generically simple torsion free \mathcal{A} -module with Hilbert polynomial P . Choose a basis of $H^0(E(m))$ and let $G \subseteq GL(N)$ be the scheme-theoretic stabilizer of the corresponding point in $R(k)$. It suffices to show that G and \mathbb{G}_m have the same set of points with values in k and in $k[\varepsilon]$ where $\varepsilon^2 = 0$.

Every point in $G(k)$ corresponds to an automorphism of E ; hence $G(k) = k^*$ because E has only scalar endomorphisms.

Similarly, every point in $G(k[\varepsilon])$ corresponds to an automorphism of the constant family $E[\varepsilon]$ over $\text{Spec } k[\varepsilon]$. Restricting from $\text{Spec } k[\varepsilon]$ to $\text{Spec } k$, we get an exact sequence

$$0 \longrightarrow \text{End}_{\mathcal{A}}(E) \xrightarrow{-\varepsilon} \text{End}_{\mathcal{A}[\varepsilon]}(E[\varepsilon]) \longrightarrow \text{End}_{\mathcal{A}}(E) \longrightarrow 0;$$

again because E has only scalar endomorphisms, it implies $\text{End}(E[\varepsilon]) = k[\varepsilon]$ and hence $G(k[\varepsilon]) = k[\varepsilon]^*$.

This proves $G = \mathbb{G}_m$. □

THEOREM 2.3. *If $l \gg m$, then every point of R is GIT-stable for the action of $\mathrm{SL}(N) \subset \mathrm{GL}(N)$ with respect to the linearization L_l .*

Proof. We carry the necessary parts of [7, Chapter 4.4] over to our situation. Put $V := k^N$; then the points of R correspond to quotients

$$\rho : V \otimes_k \mathcal{A}(-m) \rightarrow E.$$

We fix such a point.

Let $V' \subset V$ be a proper vector subspace, and put

$$E' := \rho(V' \otimes_k \mathcal{A}(-m)) \subseteq E.$$

Then E' is an \mathcal{A} -submodule of E with nonzero generic fibre; since E_η contains no proper \mathcal{A}_η -submodules, this implies $E'_\eta = E_\eta$. So E and E' have the same rank, i. e. their Hilbert polynomials have the same leading coefficient. Hence

$$\dim(V) \cdot \chi(E'(l)) > \dim(V') \cdot \chi(E(l)) \quad (2)$$

if l is sufficiently large. (We can find one l uniformly for all V' because the family of vector subspaces $V' \subset V$ is bounded.)

After these preliminaries, we can check that our point ρ in R satisfies the Hilbert-Mumford criterion for GIT-stability, cf.[7, Theorem 4.2.11]. So consider a nontrivial one-parameter subgroup $\lambda : \mathbb{G}_m \rightarrow \mathrm{SL}(V) = \mathrm{SL}(N)$; we will rather work with the associated eigenspace decomposition $V = \bigoplus_{n \in \mathbb{Z}} V_n$ where \mathbb{G}_m acts on V_n with weight n .

Let \bar{R} be the closure of R in the projective embedding given by L_l ; this is also the closure of R in $\mathrm{Quot}_P(V \otimes_k \mathcal{A}(-m))$ because the L_l are ample on the whole Quot-scheme. We have to look at the limit $\lim_{t \rightarrow 0} \lambda(t) \cdot \rho$ in \bar{R} . This is a fixed point for the \mathbb{G}_m -action, so \mathbb{G}_m acts on the fibre of L_l over it, necessarily with some weight $-\mu^{L_l}(\rho, \lambda) \in \mathbb{Z}$; what we have to show for stability is $\mu^{L_l}(\rho, \lambda) > 0$. First we describe the limit point $\lim_{t \rightarrow 0} \lambda(t) \cdot \rho$ as a point in the Quot-scheme. We put

$$V_{\leq n} := \bigoplus_{\nu \leq n} V_\nu \subseteq V \quad \text{and} \quad E_{\leq n} := \rho(V_{\leq n} \otimes_k \mathcal{A}(-m)) \subseteq E.$$

Then $V_n = V_{\leq n} / V_{\leq n-1}$; we put $E_n := E_{\leq n} / E_{\leq n-1}$, thus obtaining surjections

$$\rho_n : V_n \otimes_k \mathcal{A}(-m) \longrightarrow E_n.$$

Then

$$\bar{\rho} := \bigoplus_{n \in \mathbb{Z}} \rho_n : V \otimes_k \mathcal{A}(-m) \longrightarrow \bigoplus_{n \in \mathbb{Z}} E_n$$

is also a point in $\mathrm{Quot}_P(V \otimes_k \mathcal{A}(-m))$; it is the limit we are looking for:

$$\bar{\rho} = \lim_{t \rightarrow 0} \lambda(t) \cdot \rho.$$

To prove this, just copy the proof of [7, Lemma 4.4.3], replacing $\mathcal{O}_X(-m)$ by $\mathcal{A}(-m)$ everywhere.

The second step is to consider the fibre of L_l over $\bar{\rho}$. It is by definition

$$\det H^0\left(\bigoplus_{n \in \mathbb{Z}} E_n(l)\right);$$

this is canonically isomorphic to the tensor product of the determinant of cohomology of the $E_n(l)$. Now \mathbb{G}_m acts on V_n with weight n , so it acts on the fiber in question with weight

$$-\mu^{L_l}(\rho, \lambda) = \sum_{n \in \mathbb{Z}} n \cdot \chi(E_n(l)),$$

cf. [7, Lemma 4.4.4].

Finally, we use the preliminaries above to estimate this sum. If we apply (2) to $V' = V_{\leq n}$, $E' = E_{\leq n}$ and sum up, we get

$$\sum_{n \in \mathbb{Z}} (\dim(V) \cdot \chi(E_{\leq n}(l)) - \dim(V_{\leq n}) \cdot \chi(E(l))) > 0; \tag{3}$$

note that only finitely many summands are nonzero because $V_{\leq n}$ is zero or V for almost all n since almost all V_n are zero. Put

$$a_n := \dim(V) \cdot \chi(E_n(l)) - \dim(V_n) \cdot \chi(E(l));$$

again, all but finitely many of these integers are nonzero, and

$$\sum_{n \in \mathbb{Z}} a_n = \dim(V) \cdot \chi(E(l)) - \dim(V) \cdot \chi(E(l)) = 0.$$

If we write $a_{\leq n} := \sum_{\nu \leq n} a_\nu$, then

$$\sum_n a_{\leq n} + \sum_n n a_n = 0$$

because the sum of the a_n is zero. Hence (3) is equivalent to

$$\sum_{n \in \mathbb{Z}} n (\dim(V) \cdot \chi(E_n(l)) - \dim(V_n) \cdot \chi(E(l))) < 0.$$

But $\sum_n n \dim V_n = 0$ because \mathbb{G}_m acts on V with determinant 1. Thus we obtain

$$\sum_{n \in \mathbb{Z}} n (\dim(V) \cdot \chi(E_n(l))) < 0,$$

i. e. $-\mu^{L_l}(\rho, \lambda) \cdot \dim(V) < 0$. This proves that the Hilbert-Mumford criterion for GIT-stability is satisfied here. \square

Now we can state our main result. See [15] for the concepts ‘geometric quotient’ and ‘coarse moduli scheme’.

THEOREM 2.4. *i) The action of $\mathrm{GL}(N)$ on R described in proposition 2.2.iii above admits a geometric quotient*

$$M_{\mathcal{A}/X;P} := \mathrm{GL}(N) \backslash R$$

which is a separated scheme of finite type over k .

ii) The quotient morphism

$$R \longrightarrow M_{\mathcal{A}/X;P}$$

is a principal $\mathrm{PGL}(N)$ -bundle (locally trivial in the fppf-topology).

iii) $M_{\mathcal{A}/X;P}$ is a coarse moduli scheme for the moduli functor $\mathcal{M}_{\mathcal{A}/X;P}$.

iv) $M_{\mathcal{A}/X;P}$ is projective over k .

Proof. i) According to geometric invariant theory [15, Theorem 1.10 and Appendix 1.C] and theorem 2.3 above, the action of $\mathrm{SL}(N)$ on R admits a geometric quotient $M_{\mathcal{A}/X;P}$ which is quasiprojective over k . Then $M_{\mathcal{A}/X;P}$ is also a geometric quotient for the action of $\mathrm{GL}(N)$ on R because both groups act via $\mathrm{PGL}(N) = \mathrm{PSL}(N)$.

ii) This morphism is affine by its GIT-construction. According to [15, Proposition 0.9], it suffices to show that the action of $\mathrm{PGL}(N)$ on R is free, i. e. that

$$\psi : \mathrm{PGL}(N) \times R \longrightarrow R \times R, \quad (g, r) \mapsto (g \cdot r, r)$$

is a closed immersion. The fibers of ψ over k -points of $R \times R$ are either empty or isomorphic to $\mathrm{Spec} k$ by proposition 2.2.v above; furthermore, ψ is proper due to [15, Proposition 0.8]. Hence ψ is indeed a closed immersion.

iii) Part i implies that $M_{\mathcal{A}/X;P}$ is a coarse moduli scheme for the functor

$$\underline{\mathrm{GL}(N) \backslash R} : \underline{Sch}_k \longrightarrow \underline{Sets}$$

that sends a k -scheme S to the set of $\mathrm{GL}(N)(S)$ -orbits in $R(S)$. However, this functor is very close to the moduli functor $\mathcal{M} = \mathcal{M}_{\mathcal{A}/X;P}$:

We have a morphism from the functor represented by R to \mathcal{M} ; it simply forgets the extra structure. If S is a scheme over k , then two S -valued points of R have the same image in $\mathcal{M}(S)$ if and only if they are in the same $\mathrm{GL}(N)(S)$ -orbit. Thus we get a morphism of functors

$$\phi : \underline{\mathrm{GL}(N) \backslash R} \longrightarrow \mathcal{M}$$

which is injective for every scheme S over k . The image of ϕ consists of all sheaves $\mathcal{E} \in \mathcal{M}(S)$ for which the vector bundle $pr_* \mathcal{E}(m)$ over S is trivial, where $pr : X \times_k S \rightarrow S$ is the canonical projection.

In particular, ϕ is bijective whenever S is the spectrum of a field, and it induces an isomorphism between the Zariski sheafifications of both functors. It follows that $M_{\mathcal{A}/X;P}$ is also a coarse moduli scheme for the functor \mathcal{M} .

iv) We already know that $M_{\mathcal{A}/X;P}$ is quasiprojective. Furthermore, it satisfies the valuative criterion for properness by proposition 1.5. \square

In particular, the moduli functor $\mathcal{M}_{\mathcal{A}/X}$ of *all* generically simple torsion free \mathcal{A} -modules has a coarse moduli scheme

$$M_{\mathcal{A}/X} = \coprod_P M_{\mathcal{A}/X;P}$$

which is a disjoint sum of projective schemes over k . If X is smooth of dimension d , then we have another such decomposition

$$M_{\mathcal{A}/X} = \coprod_{c_1, \dots, c_d} M_{\mathcal{A}/X; c_1, \dots, c_d}$$

given by fixing the Chern classes $c_i \in CH^i(X)$, the Chow group of cycles modulo *algebraic* equivalence. Indeed, each $M_{\mathcal{A}/X; c_1, \dots, c_d}$ is open and closed in some $M_{\mathcal{A}/X;P}$ where P is given by Hirzebruch-Riemann-Roch.

If X is a smooth projective surface, then this decomposition reads

$$M_{\mathcal{A}/X} = \coprod_{\substack{c_1 \in NS(X) \\ c_2 \in \mathbb{Z}}} M_{\mathcal{A}/X; c_1, c_2}.$$

3 DEFORMATIONS AND SMOOTHNESS

We introduce the usual cohomology classes that describe deformations of a coherent \mathcal{A} -module E , following Artamkin [1]. By definition, a *deformation* \mathcal{E} of E over a local artinian k -algebra (A, \mathfrak{m}) with residue field k is a (flat) family \mathcal{E} of coherent \mathcal{A} -modules parameterized by $\text{Spec } A$ together with an isomorphism $k \otimes_A \mathcal{E} \cong E$.

Consider first the special case $A = k[\varepsilon]$ with $\varepsilon^2 = 0$. Then we have an exact sequence of A -modules

$$0 \longrightarrow k \xrightarrow{\cdot\varepsilon} k[\varepsilon] \longrightarrow k \longrightarrow 0. \tag{4}$$

By definition, the *Kodaira-Spencer class* of the deformation \mathcal{E} over $k[\varepsilon]$ is the Yoneda extension class

$$ks(\mathcal{E}) := [0 \longrightarrow E \xrightarrow{\cdot\varepsilon} \mathcal{E} \longrightarrow E \longrightarrow 0] \in \text{Ext}_{\mathcal{A}}^1(E, E)$$

obtained by tensoring (4) over A with \mathcal{E} .

LEMMA 3.1. *The Kodaira-Spencer map ks is a bijection between isomorphism classes of deformations of E over $k[\varepsilon]$ and elements of $\text{Ext}_{\mathcal{A}}^1(E, E)$.*

Proof. Let \mathcal{E} be an \mathcal{A} -module extension of E by E . Then \mathcal{E} becomes an $\mathcal{A}[\varepsilon]$ -module if we let ε act via the composition $\mathcal{E} \rightarrow E \hookrightarrow \mathcal{E}$. According to the local criterion for flatness [4, Theorem 6.8], \mathcal{E} is flat over $k[\varepsilon]$ and hence a deformation of E . This defines the required inverse map. \square

Now let (A, \mathfrak{m}) be arbitrary again, and let \tilde{A} be a minimal extension of A . In other words, $(\tilde{A}, \tilde{\mathfrak{m}})$ is another local artinian k -algebra with residue field k , and $A \cong \tilde{A}/(\nu)$ where $\nu \in \tilde{A}$ is annihilated by $\tilde{\mathfrak{m}}$. Then we have an exact sequence of A -modules

$$0 \longrightarrow k \xrightarrow{\cdot\nu} \tilde{\mathfrak{m}} \longrightarrow A \longrightarrow k \longrightarrow 0. \quad (5)$$

By definition, the *obstruction class* of the deformation \mathcal{E} over A is the Yoneda extension class

$$\text{ob}(\mathcal{E}; k \xrightarrow{\cdot\nu} \tilde{A} \twoheadrightarrow A) := [0 \longrightarrow E \xrightarrow{\cdot\nu} \tilde{\mathfrak{m}} \otimes_A \mathcal{E} \longrightarrow \mathcal{E} \longrightarrow E \longrightarrow 0] \in \text{Ext}_{\mathcal{A}}^2(E, E)$$

obtained by tensoring (5) over A with \mathcal{E} . Whenever we want to mention \mathcal{A} , we write $\text{ob}_{\mathcal{A}}$ instead of ob ; on the other hand, we may omit $k \xrightarrow{\cdot\nu} \tilde{A} \twoheadrightarrow A$ if they are clear from the context.

LEMMA 3.2. *The obstruction class $\text{ob}(\mathcal{E}; k \xrightarrow{\cdot\nu} \tilde{A} \twoheadrightarrow A)$ vanishes if and only if \mathcal{E} can be extended to a deformation $\tilde{\mathcal{E}}$ over \tilde{A} .*

Proof. If $\tilde{\mathcal{E}}$ is a deformation over \tilde{A} extending \mathcal{E} , then we can tensor it over \tilde{A} with the diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & k & \xrightarrow{\cdot\nu} & \tilde{\mathfrak{m}} & \longrightarrow & \mathfrak{m} & \longrightarrow & 0 \\ & & \parallel & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & k & \xrightarrow{\cdot\nu} & \tilde{A} & \longrightarrow & A & \longrightarrow & 0; \end{array}$$

this gives us a morphism of short exact sequences of \mathcal{A} -modules

$$\begin{array}{ccccccccc} 0 & \longrightarrow & E & \xrightarrow{\cdot\nu} & \tilde{\mathfrak{m}} \otimes_A \mathcal{E} & \longrightarrow & \mathfrak{m} \otimes_A \mathcal{E} & \longrightarrow & 0 \\ & & \parallel & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & E & \longrightarrow & \tilde{\mathcal{E}} & \longrightarrow & \mathcal{E} & \longrightarrow & 0. \end{array}$$

The existence of such a morphism implies $\text{ob}(\mathcal{E}; k \xrightarrow{\cdot\nu} \tilde{A} \twoheadrightarrow A) = 0$ due to the standard exact sequence

$$\dots \text{Ext}_{\mathcal{A}}^1(\mathcal{E}, E) \longrightarrow \text{Ext}_{\mathcal{A}}^1(\mathfrak{m} \otimes_A \mathcal{E}, E) \longrightarrow \text{Ext}_{\mathcal{A}}^2(E, E) \dots$$

Conversely, $\text{ob}(\mathcal{E}; k \xrightarrow{\cdot\nu} \tilde{A} \twoheadrightarrow A) = 0$ implies the existence of such a morphism of short exact sequences of \mathcal{A} -modules. Then $\tilde{\mathcal{E}}$ becomes an $\tilde{A} \otimes_k \mathcal{A}$ -module if we let any $a \in \tilde{\mathfrak{m}} \subset \tilde{A}$ act via the composition $\tilde{\mathcal{E}} \rightarrow \mathcal{E} \xrightarrow{a \otimes \cdot} \tilde{\mathfrak{m}} \otimes_A \mathcal{E} \hookrightarrow \tilde{\mathcal{E}}$. According to the local criterion for flatness [4, Theorem 6.8], $\tilde{\mathcal{E}}$ is flat over \tilde{A} and hence a deformation of E extending \mathcal{E} . \square

In the special case $A = k[\varepsilon]$ and $\tilde{A} = k[\delta]$ with $\delta^3 = 0$, we note that (5) is the Yoneda product of (4) with itself and hence

$$\text{ob}(\mathcal{E}; k \xrightarrow{\delta^2} k[\delta] \twoheadrightarrow k[\varepsilon]) = \text{ks}(\mathcal{E}) \times \text{ks}(\mathcal{E}). \tag{6}$$

From now on, we assume that X is smooth. Then we have a trace map

$$\text{tr}_{\mathcal{O}_X} : \text{Ext}_{\mathcal{O}_X}^i(E, E) \longrightarrow \text{H}^i(X, \mathcal{O}_X)$$

for every coherent \mathcal{O}_X -module E : it is defined using a finite locally free resolution of E , cf. [7, 10.1.2]. If E is a coherent \mathcal{A} -module, then we define the trace map $\text{tr} = \text{tr}_{\mathcal{A}/\mathcal{O}_X}$ as the composition

$$\text{tr} = \text{tr}_{\mathcal{A}/\mathcal{O}_X} : \text{Ext}_{\mathcal{A}}^i(E, E) \longrightarrow \text{Ext}_{\mathcal{O}_X}^i(E, E) \xrightarrow{\text{tr}_{\mathcal{O}_X}} \text{H}^i(X, \mathcal{O}_X)$$

where the first map is induced by the forgetful functor from \mathcal{A} -modules to \mathcal{O}_X -modules. Similarly, one can define a trace map

$$\text{tr}_{\mathcal{A}/\mathcal{O}_X}^{\omega_X} : \text{Ext}_{\mathcal{A}}^i(E, E \otimes_{\mathcal{O}_X} \omega_X) \longrightarrow \text{H}^i(X, \omega_X)$$

where ω_X is the canonical line bundle on X ; cf. [7, p. 218].

Now suppose that \mathcal{E} is a deformation of E over A . Then we have a line bundle $\det \mathcal{E}$ over $X_A = X \times_k \text{Spec } A$: it is defined using a finite locally free resolution of \mathcal{E} as an \mathcal{O}_{X_A} -module, cf. [7, 1.1.17 and Proposition 2.1.10].

PROPOSITION 3.3. *If \tilde{A} is a minimal extension of A , then*

$$\text{tr}(\text{ob}_{\mathcal{A}}(\mathcal{E}; k \hookrightarrow \tilde{A} \twoheadrightarrow A)) = \text{ob}_{\mathcal{O}_X}(\det \mathcal{E}; k \hookrightarrow \tilde{A} \twoheadrightarrow A) \in \text{H}^2(X, \mathcal{O}_X).$$

In particular, $\text{tr}(\text{ob}_{\mathcal{A}}(\mathcal{E})) = 0$ if the Picard variety $\text{Pic}(X)$ is smooth.

Proof. The forgetful map $\text{Ext}_{\mathcal{A}}^2(E, E) \rightarrow \text{Ext}_{\mathcal{O}_X}^2(E, E)$ maps $\text{ob}_{\mathcal{A}}(\mathcal{E})$ to $\text{ob}_{\mathcal{O}_X}(\mathcal{E})$ by definition. It is known that $\text{tr}_{\mathcal{O}_X}$ maps the latter to $\text{ob}_{\mathcal{O}_X}(\det \mathcal{E})$; cf. Artamkin’s paper [1] for the computation. \square

For the rest of this section, we assume that \mathcal{A} is even a sheaf of Azumaya algebras over the smooth projective variety X of dimension d .

PROPOSITION 3.4. *Every coherent sheaf E of \mathcal{A} -modules has a resolution of length $\leq d = \dim(X)$ by locally projective sheaves of \mathcal{A} -modules.*

Proof. If m is sufficiently large, then the twist $E(m)$ is generated by its global sections; this gives us a surjection ∂_0 of $E_0 := \mathcal{A}(-m)^N$ onto E for some N . Applying the same procedure to the kernel of ∂_0 and iterating, we obtain an infinite resolution by locally free \mathcal{A} -modules

$$\dots E_d \xrightarrow{\partial_d} E_{d-1} \dots E_1 \xrightarrow{\partial_1} E_0 \xrightarrow{\partial_0} E.$$

We claim that the image of ∂_d is locally projective over \mathcal{A} ; then we can truncate there, and the proposition follows.

It suffices to check this claim over the complete local rings $\hat{\mathcal{O}}_{X,x}$ at the closed points x of X ; there \mathcal{A} becomes a matrix algebra $\hat{\mathcal{A}}_x$, so the resulting $\hat{\mathcal{A}}_x$ -modules $\hat{E}_{i,x}$ are Morita equivalent to $\hat{\mathcal{O}}_{X,x}$ -modules. Since $\hat{\mathcal{O}}_{X,x}$ has homological dimension d , the image of $\partial_{d,x} : \hat{E}_{d,x} \rightarrow \hat{E}_{d-1,x}$ is projective over $\hat{\mathcal{A}}_x$. Hence the image of ∂_d is indeed locally projective over \mathcal{A} . \square

Our main tool to control the extension classes introduced above will be the following variant of Serre duality. To state it, we fix an isomorphism $H^d(X, \omega_X) \cong k$.

PROPOSITION 3.5. *We still assume that X is smooth of dimension d and that \mathcal{A} is a sheaf of Azumaya algebras. If E and E' are coherent \mathcal{A} -modules, then the Yoneda product*

$$\mathrm{Ext}_{\mathcal{A}}^i(E, E') \otimes \mathrm{Ext}_{\mathcal{A}}^{d-i}(E', E \otimes \omega_X) \longrightarrow \mathrm{Ext}_{\mathcal{A}}^d(E, E \otimes \omega_X)$$

followed by the trace map

$$\mathrm{tr}_{\mathcal{A}/\mathcal{O}}^{\omega_X} : \mathrm{Ext}_{\mathcal{A}}^d(E, E \otimes \omega_X) \longrightarrow H^d(X, \omega_X) \cong k$$

defines a perfect pairing of finite-dimensional vector spaces over k .

Proof. We start with the special case that E and E' are locally projective over \mathcal{A} . Then the Ext-groups in question are Zariski cohomology groups of the locally free \mathcal{O}_X -module sheaves $\mathrm{Hom}_{\mathcal{A}}(E, E')$ and $\mathrm{Hom}_{\mathcal{A}}(E', E) \otimes \omega_X$. But $\mathrm{Hom}_{\mathcal{A}}(E, E')$ and $\mathrm{Hom}_{\mathcal{A}}(E', E)$ are dual to each other by means of an appropriate local trace map, using the fact that the trace map $\mathcal{A} \otimes_{\mathcal{O}_X} \mathcal{A} \rightarrow \mathcal{O}_X$ is nowhere degenerate because \mathcal{A} is Azumaya. Hence this special case follows from the usual Serre duality theorem for locally free \mathcal{O}_X -modules.

If E and E' are not necessarily locally projective over \mathcal{A} , then we choose finite locally projective resolutions, using proposition 3.4. Induction on their length reduces us to the case where E and E' have resolutions of length one by \mathcal{A} -modules for which the duality in question holds. Now $\mathrm{Ext}_{\mathcal{A}}^i(E, E')$ and $\mathrm{Ext}_{\mathcal{A}}^{d-i}(E', E \otimes \omega)^{\mathrm{dual}}$ are δ -functors in both variables E and E' , and the pairing defines a morphism between them. An application of the five lemma to the resulting morphisms of long exact sequences proves the required induction step. \square

THEOREM 3.6. *Let X be an abelian or K3 surface over k , and let \mathcal{A} be a sheaf of Azumaya algebras over X . Suppose $\mathcal{A}_\eta \cong \mathrm{Mat}(n \times n; D)$ for a central division algebra D of dimension r^2 over the function field $k(X)$.*

- i) The moduli space $M_{\mathcal{A}/X}$ of generically simple torsion free \mathcal{A} -modules E is smooth.*

- ii) *There is a nowhere degenerate alternating 2-form on the tangent bundle of $M_{\mathcal{A}/X}$.*
- iii) *If $r \geq 2$, then the open locus $M_{\mathcal{A}/X}^{\text{lp}}$ of locally projective \mathcal{A} -modules E is dense in $M_{\mathcal{A}/X}$.*
- iv) *If we fix the Chern classes $c_1 \in \text{NS}(X)$ and $c_2 \in \mathbb{Z}$ of E , then*

$$\dim M_{\mathcal{A}/X; c_1, c_2} = \Delta / (nr)^2 - c_2(\mathcal{A})/n^2 - r^2\chi(\mathcal{O}_X) + 2$$

where $\Delta = 2r^2nc_2 - (r^2n - 1)c_1^2$ is the discriminant of E .

Proof. i) We have to check that all obstruction classes

$$\text{ob}_{\mathcal{A}}(\mathcal{E}; k \hookrightarrow \tilde{A} \twoheadrightarrow A) \in \text{Ext}_{\mathcal{A}}^2(E, E)$$

vanish. $\text{Pic}(X)$ is known to be smooth; using proposition 3.3, it suffices to show that the trace map

$$\text{tr}_{\mathcal{A}/\mathcal{O}_X} : \text{Ext}_{\mathcal{A}}^2(E, E) \longrightarrow H^2(X, \mathcal{O}_X)$$

is injective. But it is straightforward to check that this map is Serre-dual to the natural map

$$H^0(X, \omega_X) \longrightarrow \text{Hom}_{\mathcal{A}}(E, E \otimes \omega_X),$$

which is an isomorphism because ω_X is trivial and E has only scalar endomorphisms.

ii) Mukai's argument in [14] carries over to our situation as follows. We fix an isomorphism $\omega_X \cong \mathcal{O}_X$. The Kodaira-Spencer map identifies the tangent space $T_{[E]}M_{\mathcal{A}/X}$ with $\text{Ext}_{\mathcal{A}}^1(E, E)$. On this vector space, the Serre duality 3.5 defines a nondegenerate bilinear form. Indeed, this form is just the Yoneda product

$$\text{Ext}_{\mathcal{A}}^1(E, E) \otimes \text{Ext}_{\mathcal{A}}^1(E, E) \longrightarrow \text{Ext}_{\mathcal{A}}^2(E, E);$$

the right hand side is isomorphic to k by Serre duality again. Equation (6) implies that this bilinear form is alternating because all obstruction classes vanish here.

iii) Let E be a generically simple torsion free \mathcal{A} -module, and let $\text{Quot}_l(E/\mathcal{A})$ be the moduli scheme of quotients $E \twoheadrightarrow T$ where T is a coherent \mathcal{A} -module of finite length l . This is a closed subscheme of Grothendieck's Quot-scheme $\text{Quot}_{l, nr}(E)$ parameterizing those exact sequences of coherent sheaves $0 \rightarrow E' \rightarrow E \rightarrow T \rightarrow 0$ for which E' is an \mathcal{A} -submodule, i. e. the composition

$$\mathcal{A} \otimes E' \hookrightarrow \mathcal{A} \otimes E \twoheadrightarrow E \twoheadrightarrow T$$

vanishes; here $(nr)^2 = \text{rk}(\mathcal{A})$. In particular, $\text{Quot}_l(E/\mathcal{A})$ is projective over k . We show by induction that $\text{Quot}_l(E/\mathcal{A})$ is connected; cf. [7, 6.A.1].

Let $\text{Drap}_{l_1, l_2}(E/\mathcal{A})$ be the moduli scheme of iterated quotients $E \twoheadrightarrow T_1 \twoheadrightarrow T_2$ where T_i is a coherent \mathcal{A} -module of finite length l_i for $i = 1, 2$; this is again

a closed subscheme of some Flag-scheme [7, 2.A.1] and hence projective over k . Sending such an iterated quotient to T_1 and to the pair $(T_2, \text{supp}(T_1/T_2))$ defines two morphisms

$$\text{Quot}_{l+1}(E/\mathcal{A}) \xleftarrow{\theta_1} \text{Drap}_{l+1,l}(E/\mathcal{A}) \xrightarrow{\theta_2} \text{Quot}_l(E/\mathcal{A}) \times X.$$

Using Morita equivalence over the complete local rings at the support of torsion sheaves, it is easy to see that θ_1 and θ_2 are both surjective; moreover, the fibers of θ_2 are projective spaces and hence connected. This shows that $\text{Quot}_{l+1}(E/\mathcal{A})$ is connected if $\text{Quot}_l(E/\mathcal{A})$ is; thus they are all connected.

Let E still be a generically simple torsion free \mathcal{A} -module; we have to show that its connected component in $M_{\mathcal{A}/X}$ contains a locally projective \mathcal{A} -module. Let

$$E^* := \text{Hom}_{\mathcal{O}_X}(E, \mathcal{O}_X)$$

be the dual of E ; this is a sheaf of right \mathcal{A} -modules. The double dual E^{**} is a sheaf of left \mathcal{A} -modules again; it is locally free over \mathcal{O}_X and hence locally projective over \mathcal{A} . We have an exact sequence

$$0 \longrightarrow E \xrightarrow{\iota} E^{**} \xrightarrow{\pi} T \longrightarrow 0$$

where T is a coherent \mathcal{A} -module of finite length l . There is a natural map

$$\text{Quot}_l(E^{**}/\mathcal{A}) \longrightarrow M_{\mathcal{A}/X}$$

that sends a quotient to its kernel; since $\text{Quot}_l(E^{**}/\mathcal{A})$ is connected, we may assume that T is as simple as possible, i. e. that its support consists of l distinct points $x_1, \dots, x_l \in X$ where the stalks T_{x_i} are Morita-equivalent to coherent skyscraper sheaves of length one.

In this situation, we adapt an argument of Artamkin [2] to show that E can be deformed to a locally projective \mathcal{A} -module if $r \geq 2$. We consider the diagram

$$\begin{array}{ccccc} \text{Ext}_{\mathcal{A}}^1(E, E) & \xrightarrow{\delta} & \text{Ext}_{\mathcal{A}}^2(T, E) & \xrightarrow{\pi^*} & \text{Ext}_{\mathcal{A}}^2(E^{**}, E) \\ & & \downarrow \iota_* & & \\ & & \text{Ext}_{\mathcal{A}}^2(T, E^{**}) & \xlongequal{\quad} & \bigoplus_{i=1}^l \text{Ext}_{\mathcal{A}}^2(T_{x_i}, E^{**}). \end{array}$$

Here π^* is Serre-dual to $\pi_* : \text{Hom}_{\mathcal{A}}(E, E^{**}) \rightarrow \text{Hom}_{\mathcal{A}}(E, T)$ because $\omega_X \cong \mathcal{O}_X$. But the only morphisms from E to E^{**} are the multiples of ι ; hence $\pi^* = 0$, and the connecting homomorphism δ from the long exact sequence is surjective. ι_* corresponds under Serre duality and Morita equivalence to the direct sum of the restriction maps

$$\text{Hom}_{\mathcal{O}_{x_i}}(\mathcal{O}_{x_i}^r, k_{x_i}) \longrightarrow \text{Hom}_{\mathcal{O}_{x_i}}(\mathfrak{m}_{x_i} \oplus \mathcal{O}_{x_i}^{r-1}, k_{x_i})$$

where $\mathcal{O}_x = \hat{\mathcal{O}}_{X,x}$ is the complete local ring of X at x , $\mathfrak{m}_x \subseteq \mathcal{O}_x$ is its maximal ideal, and $k_x = \mathcal{O}_x/\mathfrak{m}_x$ is the residue field. Assuming $r \geq 2$, these restriction maps are obviously nonzero.

Hence there is a class $\xi \in \text{Ext}_{\mathcal{A}}^1(E, E)$ whose image in $\text{Ext}_{\mathcal{A}}^2(T_{x_i}, E^{**})$ is nonzero for all i . Since all obstruction classes vanish, we can find a deformation \mathcal{E} of E over a smooth connected curve whose Kodaira-Spencer class is ξ ; it remains to show that a general fiber E' of \mathcal{E} is locally projective over \mathcal{A} .

Forming the double dual, we get an exact sequence

$$0 \longrightarrow E' \longrightarrow (E')^{**} \longrightarrow T' \longrightarrow 0.$$

An explicit computation using Morita equivalence shows that the forgetful map

$$k^r \cong \text{Ext}_{\mathcal{A}}^2(T_{x_i}, E^{**}) \longrightarrow \text{Ext}_{\mathcal{O}_X}^2(T_{x_i}, E^{**}) \cong k^{n^2 r^3}$$

is injective. Hence the Kodaira-Spencer class of \mathcal{E} in $\text{Ext}_{\mathcal{O}_X}^1(E, E)$ also has nonzero image in $\text{Ext}_{\mathcal{O}_X}^2(T_{x_i}, E^{**})$ for all i . According to [2, Corollary 1.3 and the proof of Lemma 6.2], this implies that E' is less singular than E , i.e. the length of T' as an \mathcal{O}_X -module is strictly less than nr at every point of its support. But T' is an \mathcal{A} -module, so these lengths are all divisible by nr ; hence $T' = 0$, and E' is locally projective over \mathcal{A} .

iv) Using i and iii, it suffices to compute the dimension of

$$T_{[E]}M_{\mathcal{A}/X} \cong \text{Ext}_{\mathcal{A}}^1(E, E) \cong H^1(\text{End}_{\mathcal{A}}(E))$$

for a generically simple locally projective \mathcal{A} -module E . Note that H^0 and H^2 are Serre-dual to each other and hence both one-dimensional here.

The endomorphism sheaf $\text{End}_{\mathcal{A}}(E)$ is an Azumaya algebra of rank r^2 over X , and the natural map

$$\mathcal{A} \otimes_{\mathcal{O}_X} \text{End}_{\mathcal{A}}(E) \longrightarrow \text{End}_{\mathcal{O}_X}(E)$$

is an isomorphism; this is easily checked by reducing to the case that \mathcal{A} is a matrix algebra. Furthermore, $c_1(\mathcal{A})$ is numerically equivalent to zero because $\mathcal{A} \cong \mathcal{A}^{\text{dual}}$ using the trace over \mathcal{O}_X ; similarly, $c_1(\text{End}_{\mathcal{A}}(E))$ and $c_1(\text{End}_{\mathcal{O}_X}(E))$ are also numerically equivalent to zero. Using this, the formalism of Chern classes yields

$$r^2 c_2(\mathcal{A}) + (nr)^2 c_2(\text{End}_{\mathcal{A}}(E)) = \Delta \tag{7}$$

where Δ is the discriminant of E as above. Hence

$$\chi(\text{End}_{\mathcal{A}}(E)) = -\Delta/(nr)^2 + c_2(\mathcal{A})/n^2 + r^2 \chi(\mathcal{O}_X)$$

by Hirzebruch-Riemann-Roch. □

4 LEFT AND RIGHT ORDERS

We still assume that X is smooth projective of dimension d and that \mathcal{A} is a sheaf of Azumaya algebras over X ; furthermore, we suppose that the generic fiber \mathcal{A}_η is a division algebra D of dimension r^2 over $k(X)$. In this case, generically simple locally projective \mathcal{A} -modules are just locally free \mathcal{A} -modules of rank one; of course every such \mathcal{A} -module E can be embedded into D . The endomorphism sheaf of such a left \mathcal{A} -module E is then just an order in D acting by right multiplication on E , exactly as in the classical picture of the Brandt groupoid [3, VI, §2, Satz 14].

The Picard group $\text{Pic}(X)$ acts on the moduli scheme $M_{\mathcal{A}/X}$ by tensor product: a line bundle $L \in \text{Pic}(X)$ acts as $E \mapsto E \otimes_{\mathcal{O}_X} L$. The projective group scheme $\text{Pic}^0(X)$ of line bundles L algebraically equivalent to zero acts on the individual pieces $M_{\mathcal{A}/X; c_1, \dots, c_d}$ because $c_i(E \otimes L) = c_i(E)$ for all i . The same remarks hold for

$$M_{\mathcal{A}/X}^{\text{lp}} = \prod_{c_1, \dots, c_d} M_{\mathcal{A}/X; c_1, \dots, c_d}^{\text{lp}}$$

where the superscript lp denotes the open locus of locally projective (and hence locally free) \mathcal{A} -modules.

PROPOSITION 4.1. *There is a geometric quotient of $M_{\mathcal{A}/X}^{\text{lp}}$ by the action of $\text{Pic}(X)$; it is a disjoint sum of separated schemes of finite type over k . Its closed points correspond bijectively to isomorphism classes of Azumaya algebras over X with generic fiber D .*

Proof. $\text{Pic}(X)$ acts with finite stabilizers; this follows from

$$\det(E \otimes L) \cong \det(E) \otimes L^{\otimes r^2}. \quad (8)$$

For fixed Chern classes c_1, \dots, c_d , let $G \subseteq \text{Pic}(X)$ be the subgroup of all line bundles L that map $M_{\mathcal{A}/X; c_1, \dots, c_d}^{\text{lp}}$ to $M_{\mathcal{A}/X; c_1, \dots, c_d}^{\text{lp}}$. Then G contains $\text{Pic}^0(X)$, and its image in $\text{NS}(X) = \text{Pic}(X)/\text{Pic}^0(X)$ is contained in the r^2 -torsion and hence finite, so G is a projective group scheme. Therefore a geometric quotient of $M_{\mathcal{A}/X; c_1, \dots, c_d}^{\text{lp}}$ by G exists and is separated and of finite type over k , according to [6, Exposé V, Théorème 7.1].

It remains to construct the announced bijection. As

$$\text{End}_{\mathcal{A}}(E)^{\text{op}} \cong \text{End}_{\mathcal{A}}(E \otimes L)^{\text{op}} =: \mathcal{A}',$$

which is again an Azumaya algebra with generic fiber D , we obtain a well defined map from closed points of the quotient to isomorphism classes of such \mathcal{A}' . Conversely, given $\mathcal{A}, \mathcal{A}'$, the possible locally free \mathcal{A} -modules E of rank one with $\text{End}_{\mathcal{A}}(E)^{\text{op}} \cong \mathcal{A}'$ all differ only by tensoring with line bundles. This can be seen as follows:

Suppose that E and E' are locally free \mathcal{A} -modules of rank one with

$$\text{End}_{\mathcal{A}}(E)^{\text{op}} \cong \text{End}_{\mathcal{A}}(E')^{\text{op}} \cong \mathcal{A}'.$$

We choose embeddings of E and E' into $\mathcal{A}_\eta = D$; this also embeds $End_{\mathcal{A}}(E)^{op}$ and $End_{\mathcal{A}}(E')^{op}$ into D . The given isomorphism between them induces an automorphism of D , i. e. conjugation with an element of D ; altering the embedding $E' \hookrightarrow D$ by a right multiplication with this element, we may assume that $End_{\mathcal{A}}(E)^{op} = End_{\mathcal{A}}(E')^{op} =: \mathcal{A}'$ as subalgebras of D .

There is an open subscheme $U \subseteq X$ such that $\mathcal{A}|_U = E|_U = E'|_U = \mathcal{A}'|_U$. Furthermore, $X \setminus U$ is a finite union of divisors D_1, \dots, D_l ; it is enough to study the question at the generic points x_i of the D_i . There the local ring \mathcal{O}_{X,x_i} is a discrete valuation ring; over its completion $\hat{\mathcal{O}}_{X,x_i}$, \mathcal{A} becomes isomorphic to a matrix algebra, so we can describe the situation using Morita equivalence as follows:

$\hat{E}_{x_i}, \hat{E}'_{x_i}$ correspond to lattices over $\hat{\mathcal{O}}_{X,x_i}$ in $F_{x_i}^r$ (F_{x_i} the completion of F at x_i) such that $End_{\hat{\mathcal{O}}_{x_i}}(\hat{E}_{x_i})^{op} = End_{\hat{\mathcal{O}}_{x_i}}(\hat{E}'_{x_i})^{op} = \hat{\mathcal{A}}'_{x_i}$. But then it is an easy exercise to see that $\hat{E}'_{x_i} = \pi_i^{N_i} \hat{E}_{x_i}$ for some $N_i \in \mathbb{Z}$ where $\pi_i \in \hat{\mathcal{O}}_{x_i}$ is a uniformising element. From this our claim follows.

This shows that the map above is injective. For the surjectivity, we consider two Azumaya algebras $\mathcal{A}, \mathcal{A}' \subseteq D$ and define $E(U) := \{f \in D : \mathcal{A}|_U \cdot f \subseteq \mathcal{A}'|_U\}$. Using Morita equivalence as above, it is easy to check that E is a locally free \mathcal{A} -module of rank one with $End_{\mathcal{A}}(E)^{op} = \mathcal{A}'$; this proves the surjectivity. \square

REMARK 4.2. If \mathcal{A}' is another sheaf of Azumaya algebras over X with generic fiber $\mathcal{A}'_\eta \cong D = \mathcal{A}_\eta$, then the moduli spaces $M_{\mathcal{A}/X}$ and $M_{\mathcal{A}'/X}$ are isomorphic. Indeed, the preceding proof shows that there is a locally free \mathcal{A} -module E of rank one with $End_{\mathcal{A}}(E)^{op} \cong \mathcal{A}'$; then E is a right \mathcal{A}' -module, and one checks easily that the functor $E \otimes_{\mathcal{A}'}$ - defines an equivalence from left \mathcal{A}' -modules to left \mathcal{A} -modules.

REMARK 4.3. If X is a surface, then this quotient can be decomposed explicitly into pieces of finite type as follows:

The action of $Pic(X)$ preserves the discriminant $\Delta(E) \in \mathbb{Z}$, so we get a decomposition

$$M_{\mathcal{A}/X}^{lp}/Pic(X) = \coprod_{\Delta \in \mathbb{Z}} M_{\mathcal{A}/X;\Delta}^{lp}/Pic(X).$$

Now the first Chern class $c_1(E) \in NS(X)$ decomposes $M_{\mathcal{A}/X;\Delta}^{lp}$ into pieces of finite type. But $c_1(E \otimes L) = c_1(E) + r^2 c_1(L)$, and $r^2 NS(X)$ has finite index in $NS(X)$, so $M_{\mathcal{A}/X;\Delta}^{lp}/Pic(X)$ is indeed of finite type over k .

According to equation (7), fixing $\Delta(E)$ corresponds to fixing $c_2(\mathcal{A}') \in \mathbb{Z}$ where $\mathcal{A}' = End_{\mathcal{A}}(E)^{op}$. If X is an abelian or K3 surface, then theorem 3.6.iv yields

$$\dim M_{\mathcal{A}/X;\Delta}^{lp}/Pic(X) = c_2 - (r^2 - 1)\chi(\mathcal{O}_X)$$

where $c_2 = c_2(\mathcal{A}') = \Delta/r^2 - c_2(\mathcal{A}) \in \mathbb{Z}$ is the second Chern class of the Azumaya algebras \mathcal{A}' that this quotient parameterizes.

REMARK 4.4. M. Lieblich [13, 12] has compactified such moduli spaces of Azumaya algebras using his generalized Azumaya algebras, i. e. algebra objects in a derived category corresponding to endomorphism algebras of torsion free rank one \mathcal{A} -modules.

REMARK 4.5. Since the automorphism group of the matrix algebra $\text{Mat}(r \times r)$ is $\text{PGL}(r)$, Azumaya algebras of rank r^2 correspond to principal $\text{PGL}(r)$ -bundles. Moduli spaces for the latter have recently been constructed and compactified by T. Gomez, A. Langer, A. Schmitt and I. Sols [5].
