

Differentiable and algebroid cohomology, Van Est isomorphisms, and characteristic classes

Marius Crainic

Abstract. In the first section we discuss Morita invariance of differentiable/algebroid cohomology.

In the second section we extend the Van Est isomorphism to groupoids. As a first application we clarify the connection between differentiable and algebroid cohomology (proved in degree 1, and conjectured in degree 2 by Weinstein–Xu [50]). As a second application we extend Van Est’s argument for the integrability of Lie algebras. Applied to Poisson manifolds, this immediately implies the integrability criterion of Hector–Dazord [14].

In the third section we describe the relevant characteristic classes of representations, living in algebroid cohomology, as well as their relation to the Van Est map. This extends Evens–Lu–Weinstein’s characteristic class θ_L [20] (hence, in particular, the modular class of Poisson manifolds), and also the classical characteristic classes of flat vector bundles [2, 30].

In the last section we describe applications to Poisson geometry.

Keywords. Groupoids, Lie algebroids, Van Est isomorphism, cohomology, characteristic classes, Poisson geometry.

Introduction

The classical Van Est isomorphism [18, 17, 19] is the main tool which relates the differentiable cohomology of Lie groups to the cohomology of Lie algebras. This paper grew out of author’s attempts to understand the differentiable cohomology of groupoids, the cohomology of Lie algebroids, as well as the relations between them.

Lie groupoids/algebroids [32] have proven to be very useful in several areas: foliation theory [13, 27, 8] Poisson geometry [48, 50], non-commutative geometry [8], analysis on singular spaces [43, 44], geometry of connections etc. Roughly speaking, a Lie groupoid consists of a base manifold (the space of objects) and a “group of symmetries” (the space of arrows). Lie algebroids are the infinitesimal version of Lie groupoids. In contrast with Lie algebras, there is no Lie third theorem for

Lie algebroids. Moreover, it seems we are quite far from a complete understanding of this failure. Positive integrability results are however very important, e.g. for geometric quantization, the geometry of foliations, analysis on singular spaces.

Although differentiable/algebroid cohomology are straightforward extensions of the corresponding notions for Lie groups, they are extremely relevant when applied to the list of examples above. Particular cases are: De Rham cohomology, Lie algebra cohomology, Poisson cohomology, foliated cohomology, certain cohomology groups of classifying spaces. Despite this, very little is known about the properties/relevance of these cohomologies for general Lie groupoids. What basic properties do they enjoy (e.g. are they Morita invariant)? Which is the relation between differentiable and algebroid cohomology? Which are the invariants which live in these cohomologies? Apart from being basic questions on the theory of Lie groupoids/algebroids, they are also relevant to the applications of the general theory. For instance, in Poisson geometry, the relation between differentiable and algebroid cohomology is relevant in the process of quantizing Poisson manifolds [50]. In the same direction, one knows [20] that the modular class of Poisson manifolds lives in the world of Lie algebroids, and appears as the (first) characteristic class of a one dimensional representation. In non-commutative geometry, the cyclic cohomology of convolution algebras is undoubtedly related to differentiable cohomology of groupoids (this is clear for instance from [9, 42]); in this direction, note that one of the missing steps for extending the results of [42] from Lie groups to Lie groupoids is the lack of Van Est-type techniques for groupoids. Also, there are clear indications that cohomological methods might be useful to the integrability problem. The best example is probably Van Est's proof [17] of Lie's third fundamental theorem.

The purpose of this paper is to study these general properties of differentiable/algebroid cohomology, and to describe some applications. Below we give an outline of the main results, as well as of the relation with other known results/conjectures. Note that all the applications to Poisson geometry have been collected in the last section.

Morita invariance: Intuitively, two groupoids are Morita equivalent if they have the same space of orbits (i.e. the same transversal geometry). This notion is important in the theory of foliations (where groupoids are often replaced by Morita equivalent ones; see e.g. [13, 27]), non-commutative geometry (recall that the C^* -algebras defined by two Morita equivalent groupoids are stably isomorphic; see [8, 40]), Poisson geometry (recall that Morita equivalent Poisson manifolds can be integrated by Morita equivalent symplectic groupoids; see [51]), and to the geometry of principal bundles (gauge groupoids are Morita equivalent to Lie groups). First we prove Morita invariance of differentiable cohomology (Theorem 1). Since the notion of Morita equivalence of Lie algebroids is a bit problematic (there are several natural, but non-equivalent definitions), we restrict ourselves to an invariance of algebroid cohomology which we find relevant to applications. This is our second theorem (Theorem 2).

Van Est isomorphisms: The next theorem is an extension of Van Est's isomorphism to groupoids (Theorem 3; see also the comments at the beginning of Section 2). This immediately implies a version of Haefliger's conjecture [26, 36] for differentiable cohomology (Corollary 1). As a first application of Theorem 3 we clarify the relation between differentiable/algebroid cohomology, via a Van Est map

$$\Phi : H_d^*(G) \longrightarrow H^*(\mathfrak{g}). \quad (1)$$

This is the object of our Theorem 4. In degree one it becomes a (slight improvement of a) theorem of Weinstein-Xu, and in degree two it proves a conjecture by the same authors (see Theorem 1.3 and the comments at page 172 of [50]). In combination with the Morita invariance, this also clarifies the invariance of Poisson cohomology (see Corollary 5), which has been known in degree one only [23].

An integrability result: In Theorem 5 we present another application of Van Est's isomorphism. We prove that, given an extension of Lie algebroids

$$0 \longrightarrow \mathfrak{l} \xrightarrow{i} \mathfrak{h} \xrightarrow{\pi} \mathfrak{g} \longrightarrow 0$$

such that \mathfrak{l} is abelian, and \mathfrak{g} admits an integration which is α -two-connected, then \mathfrak{h} is integrable. Note that, in the case of Lie algebras, this immediately implies Lie's third theorem (and this is Van Est's proof [17] mentioned above). Indeed, if \mathfrak{h} is an arbitrary Lie algebra, we can take \mathfrak{l} to be the center of \mathfrak{h} , and, since $\mathfrak{g} \subset \mathfrak{gl}(\mathfrak{h})$ by the adjoint representation, \mathfrak{g} is integrable. This shows that, quite surprisingly, the non-trivial part of Van Est's argument does extend to groupoids (see also our Remark 5). There is also strong evidence that these Van Est-techniques, combined with Cattaneo-Felder approach to integrability [7] could clarify the integrability problem (compare to the proof of Lie's third in [16]).

As an immediate consequence of our integrability result we obtain a slight improvement and a more conceptual proof of Dazord-Hector's criterion [14] for the integrability of regular Poisson manifolds (see our Corollary 4). This shows that Dazord-Hector's result is precisely Van Est's argument applied to Poisson manifolds.

Comparing with another known integrability result, the one of Moerdijk-Mrcun [37] and Nistor [43], our Theorem 5 is both stronger (since we allow Lie algebroids more general than semi-direct products), and weaker (since we have to assume abelian algebroids instead of bundles of Lie algebras). An improvement which contains both integrability results would probably give a much better understanding on Lie's third theorem for groupoids.

Characteristic classes in algebroid cohomology: The last problem that we take concerns the invariants living in algebroid cohomology. The conclusion is that, given a n -dimensional representation E of a Lie algebroid \mathfrak{g} , the Chern classes of E viewed in $H^*(\mathfrak{g})$ must vanish (Theorem 6), while new classes $u_{2k-1}(E) \in H^{2k-1}(\mathfrak{g})$, $1 \leq k \leq n$ show up. Note the analogy with Bott's vanishing theorem, and the construction of secondary characteristic classes for foliations [4]. We obtain a

characteristic map

$$U : \text{Rep}(\mathfrak{g}) \longrightarrow \mathbb{Z} \times H^{\text{odd}}(\mathfrak{g}) . \quad (2)$$

See also [25]. Part of our motivation was to extend the construction of the characteristic class θ_L found by Evens–Lu–Weinstein [20] (hence, in particular, of the modular class of a Poisson manifold), which we recover when $n = k = 1$. Although we also sketch an explicit approach (in the spirit of [2]), the way we introduce the higher u_{2k-1} 's is by extending the well-known construction [30] of characteristic classes of flat vector bundles over manifolds (which we recover in the case of tangent Lie algebroids). One advantage of our (Chern–Weil type) approach is that it can be used in the presence of other structural groups (not only GL_n). Since some possible applications of this construction are to Lie algebroids which are not integrable, or whose integrations are difficult to work with, we do everything at the algebroid level. However, when E is the representation of a Lie groupoid, we show (Theorem 7) that its characteristic classes (2) come from the differentiable cohomology via the Van Est map (1). An immediate consequence of this is the Morita invariance of the modular class of Poisson manifolds (Corollary 7), which has been known under certain conditions only (see Theorem 4.2 and the conjecture 4.6 in [24]).

Acknowledgments. All the discussion I had with K. Mackenzie and I. Moerdijk were an essential source of inspiration. Useful were also the comments that V. Ginzburg and R. L. Fernandes had on a preliminary version of this paper. Regarding R. L. Fernandes I have learned, in a late stage of my work, about his construction of characteristic classes for algebroids [22] (and for Poisson manifolds in particular [21]). Recently we have explained the connection between our approaches [10, 11] (see also our Examples 8). I have also benefited from the discussions with J. Mrcun.

1. Differentiable and algebroid cohomology

This section is an exposition of basic definitions and properties concerning groupoids, differentiable cohomology, Lie algebroids, and algebroid cohomology [26, 27, 32, 34]. It is a combinations of well-known definitions which we recall for reference, and some remarks which we find important for understanding the objects under discussion. Here we prove Morita invariance of differentiable cohomology (Theorem 1), and an invariance for algebroid cohomology (Theorem 2).

1.1. Groupoids

Recall that a *groupoid* G is a (small) category in which every arrow is invertible. We will write $G^{(0)}$ and $G^{(1)}$ for the set of objects and the set of arrows in G ,

respectively. We also say that G is a groupoid over $G^{(0)}$. The source and target maps are denoted by $\alpha, \beta : G^{(1)} \rightarrow G^{(0)}$, while $m(g, h) = g \circ h$ is the composition, and $i(g) = g^{-1}$ denotes the inverse of g . One calls G a *Lie groupoid* if $G^{(0)}$ and $G^{(1)}$ are smooth manifolds, all the structure maps are smooth, and α and β are submersions. We denote by $G^{(p)}$ the space of p -composable strings

$$x \xleftarrow{g_1} \xleftarrow{g_2} \dots \xleftarrow{g_p} \tag{3}$$

and by

$$\beta = \beta_p : G^{(p)} \rightarrow G^{(0)} \tag{4}$$

the map which associates to a string (3) the element x .

A *left action* of G on a manifold X consists of a smooth map $\epsilon : X \rightarrow G^{(0)}$ called *the moment map* of the action, together with a smooth map $G^{(1)} * X \rightarrow X$, $(g, x) \mapsto gx$ defined on the space of pairs $\{(g, x) : \alpha(g) = \epsilon(x)\}$, which satisfies the usual identities of an action. One defines the action groupoid $G \ltimes X$ as the groupoid over X with $G^{(1)} * X$ as space of arrows, the multiplication as source map, the second projection as target map, and multiplication $(g, x)(h, y) = (gh, y)$ (defined when $x = hy$). A *left G -bundle* consists of a (left) G -space P , and a G -invariant surjective submersion $\pi : P \rightarrow B$. It is called *principal* if

$$G * P \rightarrow P \times_B P, \quad (g, p) \mapsto (gp, p)$$

is a diffeomorphism. Similarly one defines the notion of a right action of G on a space X , the action groupoid $X \rtimes G$, and the notion of right G -bundle.

A *morphism* between two Lie groupoids is a smooth functor. If one is interested in the orbit space rather than on the groupoid itself (i.e. in “transversal structures”), one has to relax the notion of morphism. Recall [27, 41] that a *generalized morphism* $\phi : G \rightarrow H$ between two Lie groupoids is determined by a manifold P (view it as “the graph” of ϕ) endowed with a left G -action with moment map denoted $\epsilon : P \rightarrow G^{(0)}$, a right H -action, with moment map denoted $\eta : P \rightarrow H^{(0)}$, such that $\epsilon : P \rightarrow G^{(0)}$ is a principal H -bundle, $\eta : P \rightarrow H^{(0)}$ is a G -bundle, and the two actions are compatible. The set of isomorphism classes of such P 's forms precisely the set $\text{Hom}_{\text{gen}}(G, H)$ of generalized homomorphisms from G to H . We say that P defines a *Morita equivalence* if P is principal also as a G -bundle. Given $\phi : G \rightarrow H$ represented by the bundle P , $\psi : H \rightarrow K$ represented by the bundle Q , one can define the composition $\psi \circ \phi$ represented by the bundle $P \otimes_H Q$, which is the quotient of $P \times_{H^{(0)}} Q$ by the diagonal action of H . One can easily see that Morita equivalences are precisely the isomorphisms of the resulting category.

Note that any morphism $\phi : G \rightarrow H$ can be viewed as a generalized morphism whose graph P_ϕ consists of pairs $(x, h) \in G^{(0)} \times H^{(1)}$ such that $\phi(x) = \beta(h)$, with $\epsilon(x, h) = x$, $\eta(x, h) = \alpha(h)$, and the obvious actions. We say that ϕ is an *essential equivalence* if P_ϕ defines a Morita equivalence.

Examples 1. Any Lie group is a groupoid with only one object, and any manifold can be viewed as a groupoid with identity arrows only. Any surjective submersion $\pi : M \rightarrow B$ induces a groupoid $M \times_B M$ over M , consisting on pairs $(x, y) \in M \times M$ so that $\pi(x) = \pi(y)$, with the projections as source and target, and with the obvious multiplication. One has an obvious Morita equivalence $M \times_B M \cong B$ with M as defining bundle. The particular case where B is a point gives the pair groupoid $M \times M$. The fundamental groupoid of a manifold M is Morita equivalent to the fundamental group of the manifold (take the universal cover of M as defining bundle). Any transitive groupoid is Morita equivalent to a Lie group. All these can be viewed as an instance of the gauge groupoid: given any groupoid G , and any principal G -bundle $P \rightarrow B$, one can form the gauge groupoid over P , which is $P \otimes_G P$ (we use the notations above), with the obvious structure maps; P gives a Morita equivalence $P \otimes_G P \cong G$. In (transversal) foliation theory, the holonomy and the monodromy groupoids, as well as Haefliger’s groupoids play a central role. The former one is etale (i.e. its source is a local diffeomorphism), while the first two are Morita equivalent to etale ones. In general, any foliation groupoid is Morita equivalent to an etale one [13].

Although important examples coming from foliation theory may be non-Hausdorff, in order to deal effectively with the differentiable cohomology of groupoids, we need to make the following

Overall assumption. *All groupoids G in this paper are assumed to be Hausdorff, in the sense that $G^{(0)}$ and $G^{(1)}$ are Hausdorff manifolds.*

1.2. Differentiable cohomology and Morita invariance

Let G be a Lie groupoid. A *left representation* of G is a (real or complex) vector bundle $\pi : E \rightarrow G^{(0)}$, endowed with an action of G whose moment map is precisely π , and which is fiberwise linear. Denote by $\text{Rep}(G)$ the semi-ring of isomorphism classes of (left) representations of G . An E -valued differentiable p -cochain on G is a smooth map c which associates to a string (3) an element $c(g_1, \dots, g_p) \in E_x$. The space $C_d^p(G; E)$ of p -cochains coincides with the space of smooth sections of $\beta_p^* E$, and comes equipped with a differential $d : C_d^p(G; E) \rightarrow C_d^{p+1}(G; E)$,

$$(dc)(g_1, \dots, g_p, g_{p+1}) = g_1 c(g_2, \dots, g_{p+1}) \tag{5}$$

$$+ \sum_{i=1}^p (-1)^i c(g_1, \dots, g_i g_{i+1}, \dots, g_{p+1}) + (-1)^{p+1} c(g_1, \dots, g_p). \tag{6}$$

The *differentiable cohomology* of G with coefficients in E , denoted $H_d^*(G; E)$, is defined as the cohomology of the resulting complex $(C_d^*(G; E), d)$. When E is the trivial line bundle, we simplify the notations to $C_d^*(G)$ and $H_d^*(G)$. The usual cup-product:

$$(c_1 \cup c_2)(g_1, \dots, g_{p+q}) = c_1(g_1, \dots, g_p) \otimes (g_1 \dots g_p) c_2(g_{p+1}, \dots, g_{p+q}),$$

defines a product structure $C_d(G; E) \otimes C_d(G; F) \longrightarrow C_d(G; E \otimes F)$ which passes to cohomology because it satisfies the Leibniz identity $d(c_1 \cup c_2) = d(c_1) \cup c_2 + (-1)^{\text{deg}(c_1)} c_1 \cup d(c_2)$. In particular, $(C_d^*(G), d)$ is a DG algebra, $H_d^*(G)$ is a (graded) algebra, and $H_d^*(G; E)$ are $H_d^*(G)$ -modules.

The notion of representation is a basic example of transversal structure, in the sense that any Morita equivalence $\phi : G \longrightarrow H$ induces an isomorphism $\phi^* : \text{Rep}(H) \xrightarrow{\sim} \text{Rep}(G)$. More generally, any generalized morphism $\phi \in \text{Hom}_{\text{gen}}(G, H)$ induces a map $\phi^* : \text{Rep}(H) \longrightarrow \text{Rep}(G)$, natural on ϕ . If $E \in \text{Rep}(H)$, and ϕ is represented by the bundle P , then the pull-back η^*E of the vector bundle E to P is equipped with a free right H -action, and a tautological left action of G . Define then $\phi^*E := \eta^*(E)/H$ which is a vector bundle over $P/H = G^{(0)}$, equipped with a left action of G , i.e. a representation of G .

Theorem 1. *Any Morita equivalence $\phi : G \longrightarrow H$ induces isomorphisms:*

$$\phi^* : H_d^*(H) \xrightarrow{\sim} H_d^*(G) .$$

More generally, for any $\phi \in \text{Hom}_{\text{gen}}(G, H)$, and any $E \in \text{Rep}(H)$, there is an induced homomorphism

$$\phi^* : H_d^*(H; E) \longrightarrow H_d^*(G; \phi^*E) .$$

The construction is natural on ϕ , and is compatible with the product structure. If ϕ is a morphism of groupoids, then ϕ^ is just the map induced by the composition with ϕ .*

Proof. We prove the theorem with trivial coefficients (in the general case, there are obvious modifications). Let P be a bundle representing ϕ . For each p, q , $P \times_{H^{(0)}} H^{(q)}$ is a (left) G -space, $G^{(p)} \times_{G^{(0)}} P$ is a (right) H -space. Remark that the spaces of composable arrows of the associated crossed product groupoids are related by

$$(G \bowtie (P \times_{H^{(0)}} H^{(q)}))^{(p)} = ((G^{(p)} \times_{G^{(0)}} P) \bowtie H)^{(q)} = G^{(p)} \times_{G^{(0)}} P \times_{H^{(0)}} H^{(q)} .$$

We form a double complex $C(P)$ with $C^{p,q}(P) = C^\infty(G^{(p)} \times_{G^{(0)}} P \times_{H^{(0)}} H^{(q)})$, and with the differentials defined so that the q^{th} row $C^{*,q}(P)$ is the complex computing the differential cohomology of $G \bowtie (P \times_{H^{(0)}} \times H^{(q)})$, and similarly, the p^{th} column $C^{p,*}(P)$ is the complex computing the differentiable cohomology of $(G^{(p)} \times_{G^{(0)}} P) \bowtie H$. The complexes computing the differentiable cohomologies of G and H come as co-augmentations of the columns, and rows, respectively:

$$C_d(G) \xrightarrow{\epsilon^*} C(P) \xleftarrow{\eta^*} C_d(H) .$$

We show that the condition that P is principal as an H space implies that the co-augmented columns of $C(P)$ are acyclic, hence ϵ^* induces isomorphisms in cohomology. This will give the desired map in cohomology,

$$\phi^* : H_d^*(G) \xrightarrow{(\epsilon^*)^{-1}} H^*(C(P)) \xrightarrow{\eta^*} H_d^*(H),$$

and, if P is principal also as a G -space (i.e. is a Morita equivalence), a similar argument proves that also η^* induces isomorphisms in cohomology. Since each of the groupoids $(G^{(p)} \times_{G^{(0)}} P) \rtimes H$ is diffeomorphic to a groupoid of type $X \times_B X$ (choose $X = G^{(p)} \times_{G^{(0)}} P$, $B = G^{(p)}$), the acyclicity of the columns follows from the following:

Lemma 1. *For any surjective submersion $\pi : X \rightarrow B$, and any vector bundle E on B , the differentiable cohomology $H_d^*(X \times_B X; \pi^* E)$ is zero in positive degrees, and is $C^\infty(B; E)$ in degree zero.*

Proof. We have to prove that the complex $C^* = C_d^*(X \times_B X)$, together with the co-augmentation $\pi^* : C^\infty(B) \rightarrow C^\infty(X) = C^0$, is exact. If π admits a continuous section $s : B \rightarrow X$, we have the explicit homotopy $h(c)(x_1, \dots, x_{n-1}) = c(s(\pi(x_1)), x_2, \dots, x_{n-1})$. In the general case, we choose an open cover \mathcal{U} of B over which π admits local sections, and we use a Mayer–Vietoris argument [5]. \square

To prove that ϕ^* is compatible with the product structure, it suffices to find a (bigraded) product on $C(P)$, such that ϵ^* and η^* are compatible with the products. For $c \in C^{p,q}$, $c' \in C^{p',q'}$ we define $\omega \cdot \eta \in C^{p+q,p'+q'}$ by

$$\begin{aligned} & (c \cdot c')(g_1, \dots, g_{p+p'}, x, h_1, \dots, h_{q+q'}) \\ &= c(g_1, \dots, g_p, g_{p+1} \dots g_{p+p'} x, h_1, \dots, h_q) c'(g_{p+1}, \dots, g_{p+p'}, x h_1 \dots h_q, h_{q+1}, \dots, h_{q+q'}). \end{aligned}$$

If ϕ is a morphism of groupoids, denote by $\tilde{\phi} : C_d(H) \rightarrow C_d(G)$ the composition by ϕ . To prove that $\tilde{\phi}$ induces ϕ^* in cohomology, it suffices to find a chain map $\Phi : C(P) \rightarrow C_d(G)$ (where $P = P_\phi$, see subsection 1.1) such that $\Phi \circ \epsilon^* = Id$, and $\Phi \circ \eta^* = \tilde{\phi}$. For $c \in C^{p,q}(P_\phi) = C^\infty(G^{(p)} \times_{H^{(0)}} H^{(q+1)})$ we set

$$\Phi(c)(g_1, \dots, g_{p+q}) = c(g_1, \dots, g_p, 1_{\phi(\alpha(g_p))}, \phi(g_{p+1}), \dots, \phi(g_{p+q})).$$

We now prove the naturality $\phi^* \psi^* = (\psi \phi)^*$ for $\phi \in \text{Hom}_{\text{gen}}(G, H)$, $\psi \in \text{Hom}_{\text{gen}}(H, K)$. Choose P and Q representing ϕ , and ψ , respectively, and we consider a triple complex $C(P, Q)$ with

$$C^{p,q,r}(P, Q) = C^\infty(G^{(p)} \times_{G^{(0)}} P \times_{H^{(0)}} \times H^{(q)} \times_{H^{(0)}} Q \times_{K^{(0)}} K^{(r)})$$

defined analogous to $C(P)$. The double complexes $C(P)$, $C(Q \circ P)$, and $C(Q)$ appear all as co-augmentations of $C(P, Q)$, and the first two of this co-augmentations are quasi-isomorphisms. Moreover, they are compatible with the co-augmentations of $C(P)$, $C(Q \circ P)$, and $C(Q)$, and then the conclusion follows by a diagram chasing. \square

Examples 2. When G is a Lie group, one recovers the usual differentiable cohomology of Lie groups. In particular, for discrete groups, one obtains the usual group cohomology. By Morita invariance, one can compute the differentiable cohomology in many examples: transitive groupoids, fundamental groupoids, foliation

groupoids. Related to the last class of examples, remark that if G is a Hausdorff etale groupoid, then $H_d^*(G)$ is (by definition) the same as Haefliger’s cohomology [26] with coefficients in the sheaf \mathcal{A} of smooth functions. Hence one obtains a sheaf \tilde{A} over the classifying space BG [46] so that $H_d^*(G) \cong H^*(BG; \tilde{A})$ (this was conjectured by Haefliger and proved in [36]).

1.3. From Lie groupoids to Lie algebroids

Analogous to the construction of the Lie algebra of a Lie group, one can construct the infinitesimal version of a Lie groupoid G . We recall here some of these constructions, and we refer to [32] for more details. The central role is played by the vector bundle \mathfrak{g} which is defined as the restriction along $u : G^{(0)} \hookrightarrow G^{(1)}$ of the vector bundle $T^\alpha(G^{(1)}) = Ker(d\alpha : TG^{(1)} \rightarrow TG^{(0)})$ of “ α -vertical” tangent vectors on $G^{(1)}$. The fiber of \mathfrak{g} at $x \in G^{(0)}$ is the tangent space at 1_x of $G(x, -) = \alpha^{-1}(x)$. Moreover, the differential of the target β of G induces a map of vector bundles over $G^{(0)}$, the anchor map,

$$\rho : \mathfrak{g} \longrightarrow TM.$$

Any section $X \in \Gamma(\mathfrak{g})$ defines a vector field \tilde{X} on $G^{(1)}$ by the formula

$$\tilde{X}(g) = (dR_g)_x(X(x)) ,$$

where $R_g : G(x, -) \longrightarrow G(y, -) \subset G^{(1)}$ is the right multiplication by g , $x = \beta(g)$, $y = \alpha(g)$. Denoting by $\mathcal{X}^\alpha(G) = \Gamma(T^\alpha(G^{(1)}))$ the space of “ α -vertical” vector fields on $G^{(1)}$, and by $\mathcal{X}_{inv}^\alpha(G)$ the subspace of right invariant vector fields, i.e. vector fields $X \in \mathcal{X}^\alpha(G)$ with the property that $X(gh) = (dR_h)_g(X(g))$ for all composable arrows g, h of G , the construction above defines an isomorphism:

$$\Gamma(\mathfrak{g}) \xrightarrow{\sim} \mathcal{X}_{inv}^\alpha(G) \subset \mathcal{X}(G^{(1)}), \quad X \mapsto \tilde{X} .$$

Expressing the Lie brackets in terms of flows (see below) we see that $\Gamma(\mathfrak{g}) \cong \mathcal{X}_{inv}^\alpha(G)$ is closed under the usual Lie bracket of vector fields on $G^{(1)}$. Hence $\Gamma(\mathfrak{g})$ comes equipped with a Lie bracket $[\cdot, \cdot]$, and it is not difficult to see that it is related to the anchor map by the formula:

$$[X, fY] = f[X, Y] + \rho(X)(f) \cdot Y \tag{7}$$

for all $X, Y \in \Gamma(\mathfrak{g})$ and $f \in C^\infty(G^{(0)})$. The resulting structure:

$$(\mathfrak{g}, \rho, [\cdot, \cdot])$$

is called the Lie algebroid of G .

The connection between (the sections of) \mathfrak{g} and G is given by the flows. Given $X \in \Gamma(\mathfrak{g})$, we denote by ϕ_X the flow of \tilde{X} on $G^{(1)}$, and, for $x \in G^{(0)}$, put $\beta_X(t, x) = \alpha\phi_X(t, x)$. Then β_X is a flow on $G^{(0)}$, namely the flow of the vector field $\rho(X)$, while the properties of \tilde{X} show that

$$\phi_X(t, g) = \phi_X(t, x)g, \quad \phi_X(t, x) \in G(x, \beta_X(t, x))$$

where $x = \beta(g)$. We then see that the Lie bracket in $\Gamma(\mathfrak{g})$ is given by

$$[X, Y](x) = \frac{d}{dt} \frac{d}{ds} \Big|_{t=s=0} \phi_X(t, \beta_Y(s, \beta_X(-t, x))) \phi_Y(s, \beta_X(-t, x)) \phi_X(-t, x). \tag{8}$$

An action of G on a vector bundle E over $G^{(0)}$ has an infinitesimal version:

$$L_X(s)(x) = \left(\frac{d}{dt}\right)_{t=0} \phi_X(t, x)^{-1} s(\beta_X(t, x)) \in E_x, \tag{9}$$

which defines a pairing $\Gamma(\mathfrak{g}) \times \Gamma(E) \rightarrow \Gamma(E)$, $(X, s) \mapsto L_X(s)$. These derivatives of sections of E along sections of \mathfrak{g} satisfy the basic relations:

$$L_{fX}(s) = fL_X(s) \tag{10}$$

$$L_X(fs) = fL_X(s) + L_X(f)s \tag{11}$$

$$L_{[X, Y]} = [L_X, L_Y] \tag{12}$$

for all $X, Y \in \Gamma(\mathfrak{g})$, $f \in C^\infty(G^{(0)})$, $s \in \Gamma(E)$.

1.4. Algebroids and their cohomology

A *Lie algebroid* over a manifold M is a triple

$$(\mathfrak{g}, [\cdot, \cdot], \rho)$$

consisting of a vector bundle \mathfrak{g} over M , a Lie bracket $[\cdot, \cdot]$ on the space $\Gamma(\mathfrak{g})$, and a morphism of vector bundles $\rho : \mathfrak{g} \rightarrow TM$ (*the anchor* of \mathfrak{g}), so that (7) holds true for all $X, Y \in \Gamma(\mathfrak{g})$ and $f \in C^\infty(M)$.

A *representation* of \mathfrak{g} is a vector bundle $\pi : E \rightarrow M$, together with a bilinear map (called the infinitesimal action of \mathfrak{g} on E)

$$\Gamma(\mathfrak{g}) \times \Gamma(E) \rightarrow \Gamma(E), (X, s) \mapsto L_X(s),$$

satisfying the relations (10)–(12) for all $X, Y \in \Gamma(\mathfrak{g})$, $f \in C^\infty(M)$, $s \in \Gamma(E)$. Isomorphism classes of representations of \mathfrak{g} , with the direct sum, and tensor product as operations, form a semi-ring $\text{Rep}(\mathfrak{g})$. It actually comes endowed with an involution $*$: E^* is the dual of the conjugate of E (hence, in the real case it is just the dual of E), with $L_X(\omega)(s) = L_X(\omega(s)) - \omega(L_X(s))$, for $\omega \in \Gamma(E^*)$, $s \in \Gamma(E)$. With this, a metric on E is called invariant if the induced isomorphism of vector bundles $E^* \cong E$ is compatible with the action of \mathfrak{g} .

Of course, the motivating example is the Lie algebroid of a Lie groupoid G , and the representations induced by the representations of G . As terminology, we call integration of \mathfrak{g} , any Lie groupoid G so that $\mathfrak{g} = \text{Lie}(G)$. In contrast with the theory of Lie groups, not all Lie algebroids are integrable. See however [37] for a large class of positive results. For instance one knows that, if \mathfrak{g} is integrable, then it has a unique integration G which is α -simply connected (i.e. whose α -fibers are simply connected). Moreover, in this case any representation E of \mathfrak{g} can be uniquely integrated to a representation of G (this is e.g. a very particular case of Theorem 3.6 in [37]); hence one has an isomorphism $\text{Rep}(G) \cong \text{Rep}(\mathfrak{g})$.

Let E be a representation of the Lie algebroid \mathfrak{g} . An E -valued p -cochain on \mathfrak{g} is a $C^\infty(M)$ -multilinear antisymmetric map

$$\Gamma(\mathfrak{g}) \times \dots \times \Gamma(\mathfrak{g}) \ni (X_1, \dots, X_p) \mapsto \omega(X_1, \dots, X_p) \in \Gamma(E).$$

The space $C^p(\mathfrak{g}; E)$ of such cochains coincides with the space of sections of the vector bundle $\Lambda^p \mathfrak{g}^* \otimes E$ over M , and comes equipped with a differential $d : C^p(\mathfrak{g}; E) \rightarrow C^{p+1}(\mathfrak{g}; E)$,

$$\begin{aligned} d(\omega)(X_1, \dots, X_{p+1}) &= \sum_{i < j} (-1)^{i+j-1} \omega([X_i, X_j], X_1, \dots, \hat{X}_i, \dots, \hat{X}_j, \dots, X_{p+1}) \\ &\quad + \sum_{i=1}^{p+1} (-1)^i L_{X_i}(\omega(X_1, \dots, \hat{X}_i, \dots, X_{p+1})). \end{aligned} \tag{13}$$

Define the cohomology of \mathfrak{g} with coefficients in E , denoted $H^*(\mathfrak{g}; E)$, as the cohomology of the resulting complex $C^*(\mathfrak{g}; E)$. When E is the trivial line bundle (with the action $L_X(f) = \rho(X)(f)$, $X \in \Gamma(\mathfrak{g})$, $f \in C^\infty(M)$), we simplify the notations to $C^*(\mathfrak{g})$ and $H^*(\mathfrak{g})$.

Note that, as in the case of differentiable cohomology, the usual wedge product (defined fiberwise) defines product structures $H^*(\mathfrak{g}; E) \otimes H^*(\mathfrak{g}; F) \rightarrow H^*(\mathfrak{g}; E \otimes F)$. In particular, $C^*(\mathfrak{g})$ is a DG algebra, $H^*(\mathfrak{g})$ is a (graded) algebra, and $H^*(\mathfrak{g}; E)$ are $H^*(\mathfrak{g})$ -modules. Moreover, the usual Cartan calculus extends to $C^*(\mathfrak{g})$. More precisely, any $X \in \Gamma(\mathfrak{g})$ induces Lie derivatives and interior products

$$L_X : C^*(\mathfrak{g}) \rightarrow C^*(\mathfrak{g}), \quad i_X : C^*(\mathfrak{g}) \rightarrow C^{*-1}(\mathfrak{g}),$$

$$\begin{aligned} L_X(\omega)(X_1, \dots, X_p) &= \sum \omega(X_1, \dots, X_{i-1}, [X, X_i], X_{i+1}, \dots, X_p) - \\ &\quad - L_X(\omega(X_1, \dots, X_p)) \\ i_X(\omega)(X_1, \dots, X_{p-1}) &= \omega(X, X_1, \dots, X_{p-1}). \end{aligned}$$

The Lie derivatives are derivations of degree 0, the interior products are derivations of degree -1 , and they satisfy the Cartan relations

$$di_X + i_X d = L_X \tag{14}$$

$$[L_X, L_Y] = L_{[X, Y]} \tag{15}$$

$$[L_X, i_Y] = i_{[X, Y]} \tag{16}$$

$$[i_X, i_Y] = 0. \tag{17}$$

Examples 3. Of course, Lie algebras and their cohomology are basic examples. Another extreme example is the tangent Lie algebroid TM of a manifold (when ρ is the identity). Then one recovers the usual DeRham cohomology, while its representations are precisely vector bundles over M endowed with a flat connection. Another important class of examples are the Lie algebroids associated to Poisson manifold (see section 4). Foliations (M, \mathcal{F}) can be naturally viewed as Lie algebroids with $\mathfrak{g} = \mathcal{F}$ the vectors tangent to the leaves, and ρ is the inclusion. Its

representations are precisely the foliated vector bundles over (M, \mathcal{F}) [30, 38], while its cohomology with constant coefficients is well known under the name of foliated or leafwise cohomology, denoted $H^*(\mathcal{F})$ (see e.g. [29, 38, 39, 48]). The normal bundle ν of \mathcal{F} a basic example of representation of \mathcal{F} (see below), and the cohomology $H^*(\mathcal{F}; \nu)$ is known to be relevant to deformations of foliations [28]. The α -simply connected integration of \mathcal{F} is usually called the monodromy groupoid of \mathcal{F} (see [13] for a description of all groupoids integrating \mathcal{F}). Note that when $\mathcal{F} = \mathcal{F}(\pi)$ is the foliation induced by a submersion $\pi : M \rightarrow B$ with connected fibers, then the pull-back π^*E of any vector bundle over B is naturally a representation of $\mathcal{F}(\pi)$. Moreover, if the fibers of π are simply connected, then any representation of π is of this type. Indeed, in this case the α -simply connected integration of $\mathcal{F}(\pi)$ is just $M \times_B M$, which is Morita equivalent to B (see Examples 1).

Examples 4 (Bott representations). If $E \subset \mathfrak{g}$ is an ideal (i.e. $[\Gamma E, \Gamma \mathfrak{g}] \subset \Gamma E$), on which the anchor vanishes, then $L_X(V) = [X, V]$ defines an action of \mathfrak{g} on E . If E is abelian (i.e. $[\Gamma E, \Gamma E] = 0$), then it factors through an action of $\mathfrak{h} = \mathfrak{g}/E$ on E . This applies in particular to the kernel of the anchor map of a regular Poisson manifold (see the last section).

A similar construction applies to the quotient vector bundle $\nu = \mathfrak{g}/\mathfrak{h}$, where $\mathfrak{h} \subset \mathfrak{g}$ is any Lie sub-algebroid (i.e. closed under the bracket). In this case, the Bott-type formula [4] $L_X(\bar{Y}) = \overline{[X, Y]}$ makes ν into a representation of \mathfrak{h} .

Examples 5. Let $\pi : P \rightarrow M$ be a submersion with connected fibers, and let \mathfrak{g} be a Lie algebroid over M . Recall [34] that one has an induced pull-back algebroid $\pi^!\mathfrak{g}$ over P . Its fiber at $p \in P$ consists of pairs (X, V) with $X \in \mathfrak{g}_{\pi(p)}$, $V \in T_pP$ satisfying $\rho(X) = (d\pi)_p(V)$, its anchor is $(X, V) \mapsto V$. To describe the bracket, we represent the sections of $\Gamma\pi^!\mathfrak{g}$ as sums of elements of type $\phi\pi^*(X)$, with $\phi \in C^\infty(P)$, $X \in \Gamma\mathfrak{g}$, and we put:

$$[(\phi\pi^*(X), V), (\psi\pi^*(Y), W)] = (\phi\psi\pi^*([X, Y]) + L_V(\psi)\pi^*(Y) - L_W(\phi)\pi^*(X), [V, W]).$$

(of course one has to use sums here). We leave to the reader to show that, for any $E \in \text{Rep}(\mathfrak{g})$, the pull-back bundle $\pi^*(E)$ is naturally a representation of $\pi^!\mathfrak{g}$. The map $\Gamma\mathfrak{g} \rightarrow \Gamma\pi^!\mathfrak{g}$ induces a homomorphism $H^*(\mathfrak{g}; E) \rightarrow H^*(\pi^!\mathfrak{g}; \pi^*E)$ for any representation E . Note that if π has simply connected fibers, then we have an isomorphism $\pi^* : \text{Rep}(\mathfrak{g}) \cong \text{Rep}(\pi^!\mathfrak{g})$ (use the case mentioned at the end of Examples 3, when $\mathfrak{g} = 0$ and $\pi^!(0) = \mathcal{F}(\pi)$ is the foliation defined by the fibers of π). This is only one of the reasons for which any notion of Morita equivalence for Lie algebroids should declare \mathfrak{g} and $\pi^!\mathfrak{g}$ to be equivalent. Hence the following lemma, which will be useful later, also shows that Morita invariance of cohomology can be expected under certain n -connectedness condition.

Theorem 2. *If $\pi : P \rightarrow M$ is a submersion with homologically n -connected fibers, then $\pi^* : H^k(\mathfrak{g}) \rightarrow H^k(\pi^!\mathfrak{g})$ is an isomorphism in all degrees $k \leq n$. The same holds with general coefficients.*

Proof. We first assume that $\mathfrak{g} = 0$; then $\pi^! \mathfrak{g}$ is the foliation $\mathcal{F}(\pi)$ defined by the fibers of π . In general, for any foliation \mathcal{F} on P , $H^*(\mathcal{F})$ is isomorphic to the cohomology of P with coefficients on the sheaf \mathcal{A} of smooth functions on P which are locally constant along leaves. Indeed, $U \mapsto C^*(\mathcal{F}|_U)$ are fine sheaves, and the resulting complex of sheaves is a resolution of \mathcal{A} , as can be seen by restricting to foliation charts; for more details, see e.g. [39]. In our case, \mathcal{A} is precisely the pull-back of the sheaf of smooth functions on M , and the result is a very special case of a known criterion in sheaf theory (see e.g. 1.9.4 in [1]).

In general, we need the spectral sequence associated to a sub-algebroid $\mathfrak{h} \subset \mathfrak{g}$. At the first level, it is

$$H^p(\mathfrak{h}; \Lambda^q \nu^*) \implies H^{p+q}(\mathfrak{g}) .$$

Here $\nu = \mathfrak{g}/\mathfrak{h}$ is as in Examples 4. This extends the standard spectral sequence for Lie algebras, and the well-known foliated spectral sequence [29] (when $\mathfrak{h} = \mathcal{F}$ is a foliation, and $\mathfrak{g} = TM$). To construct it, we consider the filtration $F_* C^*$ of $C^*(\mathfrak{g})$ with $F_0 C^* = C^*(\mathfrak{g})$, and, for $q \geq 1$,

$$F_q C^n = \{ \omega \in C^n(\mathfrak{g}) : \omega(X_1, \dots, X_n) = 0 \text{ if } X_1, \dots, X_{n-q+1} \in \Gamma \mathfrak{h} \} .$$

At the 0th level we clearly have $F_q C^n / F_{q+1} C^n \cong C^{n-q}(\mathfrak{h}; \Lambda^q \nu^*)$, and, a short computation shows that the boundary is precisely the one computing $H^*(\mathfrak{h}; \Lambda^q \nu^*)$.

With the notations of the statement, $\mathcal{F}(\pi)$ is obviously a Lie sub-algebroid of $\pi^! \mathfrak{g}$, and we consider the associated spectral sequence

$$E_1^{p,q} = H^p(\mathcal{F}(\pi); \pi^*(\Lambda^q \mathfrak{g}^*)) \implies H^{p+q}(\pi^! \mathfrak{g}) .$$

By the case $\mathfrak{g} = 0$ we know that $E^{p,q} = 0$ for $1 \leq p \leq n$, hence $H^k(\pi^! \mathfrak{g})$ in degrees $k \leq n$ is isomorphic to the cohomology of the complex $(H^0(\mathcal{F}(\pi); \pi^*(\Lambda^* \mathfrak{g}^*)), d_1)$, which is nothing but $C^*(\mathfrak{g})$. The rest is standard. \square

2. A Van Est isomorphism

The most general form of the Van-Est *isomorphism* states that, if a connected Lie group G acts properly (from the right) on a contractible manifold X , then

$$H_d^*(G) \cong H_{G\text{-inv}}^*(X) , \tag{18}$$

where the right hand side is the cohomology defined by the complex $\Omega^*(X)^G$ of G -invariant forms on X (cf. 5.6 in [3]). In the case where $X = G/K$ with $K \subset G$ maximal compact subgroup, $\Omega^*(G/K)^G = C^*(\mathfrak{g}, K)$ is (by definition) the complex computing the relative Lie algebra cohomology, and (18) takes the well-known form [17, 18, 19, 26] $H_d^*(G) \cong H^*(\mathfrak{g}, K)$.

In this section we improve (18), extend it to groupoids, and present some applications.

2.1. The proper case

In this subsection we prove a particular case of our general Van Est isomorphism, which is an analogue of the vanishing of $H_d^*(G)$ for compact Lie groups G . Recall that a groupoid G is called proper if the map $(\alpha, \beta) : G^{(1)} \rightarrow G^{(0)} \times G^{(0)}$ is proper.

Proposition 1. *For any proper Lie groupoid G , and any $E \in \text{Rep}(G)$,*

$$H_d^k(G; E) = 0, \quad \forall k \geq 1.$$

Proof. We fix a smooth Haar system λ for G [45], i.e. a family $\lambda = \{\lambda^x : x \in G^{(0)}\}$ of smooth measures λ^x supported on the manifolds $G(-, x) = \beta^{-1}(x)$, with the property that:

(i) for any $\phi \in C_c^\infty(G^{(1)})$, the formula

$$I_\lambda(\phi)(x) = \int_{G(-,x)} \phi(g) d\lambda^x(g)$$

defines a smooth function $I_\lambda(\phi)$ on $G^{(0)}$;

(ii) λ is left invariant, i.e., for any $g \in G(x, y)$, and any $\phi \in C_c^\infty(G(-, y))$, one has

$$\int_{G(-,x)} \phi(gh) d\lambda^x(h) = \int_{G(-,y)} \phi(h) d\lambda^y(h).$$

The existence of Haar system for Lie groupoids is well known (see e.g. the preliminaries of [13], or [44]). The properness of G ensures the existence of a “cut-off” function for G , i.e. a smooth function on $G^{(0)}$ satisfying:

(iii) $\beta : \text{supp}(c \circ \alpha) \rightarrow G^{(0)}$ is proper;

(iv) $\int_{G(-,x)} c(\alpha(g)) d\lambda^x(g) = 1$ for all $x \in G^{(0)}$.

(see e.g. the appendix in [47] for the construction of such functions). We now check that the following formula defines a contraction of $C_d^*(G; E)$:

$$h(\phi)(g_1, \dots, g_n) = \int_{G(-, \beta(g_1))} a \cdot \phi(a^{-1}, g_1, \dots, g_n) c(\alpha(a)) d\lambda^{\beta(g_1)}(a).$$

The integration is defined because of (iii) above, and defines a smooth section $h(\phi)$, by (ii) above. One has:

$$\begin{aligned} h(d(\phi))(g_1, \dots, g_n) &= \int_{G(-,x)} a \cdot \{ a^{-1} \phi(g_1, \dots, g_n) - \phi(a^{-1} g_1, g_2, \dots, g_n) - \\ &\quad - \sum_{i=1}^{n-1} (-1)^i \phi(a^{-1}, g_1, \dots, g_i g_{i+1}, \dots, g_n) + \\ &\quad + (-1)^{n+1} \phi(a^{-1}, g_1, \dots, g_{n-1}) \} c(\alpha(a)) d\lambda^x(a), \end{aligned}$$

which, by (iv) above, and the left invariance (ii) equals to

$$\begin{aligned}
 & \phi(g_1, \dots, g_n) - \int_{G(-, \beta(g_2))} g_1 a \phi(a^{-1}, g_2, \dots, g_n) c(\alpha(a)) d\lambda^{\beta(g_2)}(a) \\
 & - \sum_{i=1}^{n-1} (-1)^i \int_{G(-, \beta(g_1))} a \phi(a^{-1}, g_1, \dots, g_i g_{i+1}, \dots, g_n) c(\alpha(a)) d\lambda^{\beta(g_1)}(a) \\
 & + (-1)^{n+1} \int_{G(-, \beta(g_1))} a \phi(a^{-1}, g_1, \dots, g_n) c(\alpha(a)) d\lambda^{\beta(g_1)}(a) \\
 & = \phi(g_1, \dots, g_n) - g_1 h(\phi)(g_2, \dots, g_n) \\
 & - \sum_{i=1}^{n-1} (-1)^i h(\phi)(g_1, \dots, g_i g_{i+1}, \dots, g_n) + (-1)^{n+1} h(\phi)(g_1, \dots, g_{n-1}) \\
 & = \phi(g_1, \dots, g_n) - d(h(\phi))(g_1, \dots, g_n),
 \end{aligned}$$

hence the desired formula $hd + dh = id$. □

2.2. A Van-Est theorem

We now state and prove the extension of the Van Est isomorphism (18), mentioned at the beginning of this section.

Let P be a right G -space. We call it proper if the map $P * G^{(1)} \rightarrow P \times P$, $(g, p) \mapsto (gp, p)$ is proper. Note that, if the moment map $\pi : P \rightarrow G^{(0)}$ of the action is a submersion, then G acts on the foliation $\mathcal{F}(\pi)$ induced by π on P . More precisely, for any $p \in P$, and any arrow $g : x \rightarrow y$ of G ending at $y = \pi(p)$, the differential at p of the multiplication $\pi^{-1}(y) \rightarrow \pi^{-1}(x)$ by g induces a map

$$g : \mathcal{F}(\pi)_p \rightarrow \mathcal{F}(\pi)_{pg} . \tag{19}$$

Hence it makes sense to talk about the complex $C_G^*(\mathcal{F}(\pi))$ of G -invariant foliated forms (a subcomplex of $C^*(\mathcal{F}(\pi))$); denote by $H_G^*(\mathcal{F}(\pi))$ the resulting cohomology. Remark that the product structure on the foliated cohomology induces a product structure on $H_G^*(\mathcal{F}(\pi))$. Also, if $E \in \text{Rep}(G)$, then π^*E is a representation of $\mathcal{F}(\pi)$ (since it is a pull-back via π), and there are obvious versions with coefficients, for $C_G^*(\mathcal{F}(\pi); E)$ and $H_G^*(\mathcal{F}(\pi); E)$.

Theorem 3. *Let G be a Lie groupoid, and let P be a proper G -space whose moment map $\pi : P \rightarrow G^{(0)}$ is a submersion with connected fibers. For any $E \in \text{Rep}(G)$ there is a map compatible with the product structure*

$$\Phi_P : H_d^*(G; E) \rightarrow H_G^*(\mathcal{F}(\pi); E).$$

Moreover, if the fibers of π are cohomologically n -connected (i.e. have trivial cohomology in degrees $\leq n$), then Φ_P is an isomorphism in degrees $ \leq n$, and is injective in degree $n + 1$.*

In particular, if π has contractible fibers, then Φ_P is an isomorphism in all degrees.

Proof. We assume that the coefficients are trivial (in general there are obvious modifications). Consider the space $P * G^{(p)}$ consisting of pairs (p, \vec{g}) with $p \in P$, $\vec{g} \in G^{(p)}$ an arrow of type (3) with $\pi(p) = x$. This space comes equipped with a foliation $\mathcal{F}(p)$, defined by the projection into $G^{(p)}$. In particular, $\mathcal{F}(0) = \mathcal{F}(\pi)$. We form a double complex C which, in bi-degree (p, q) , is

$$C^{p,q} = C^q(\mathcal{F}(p)) = C^\infty(P * G^{(p)}; \Lambda^q \mathcal{F}(p)^*).$$

We now describe the differentials (but we leave to the reader the lengthy but straightforward verification of the compatibility between the horizontal and the vertical differentials).

1. Columns: the p^{th} column is just the complex $C^*(\mathcal{F}(p))$ computing the foliated cohomology. Note that it comes with $C_d^p(G)$ as a co-augmentation (as the kernel of the differential $C^0(\mathcal{F}(p)) \rightarrow C^1(\mathcal{F}(p))$):

$$0 \rightarrow C^\infty(G^{(p)}) \xrightarrow{\epsilon} C^0(\mathcal{F}(p)) \rightarrow C^1(\mathcal{F}(p)) \rightarrow \dots \tag{20}$$

2. Rows: the q^{th} row comes with $C_G^q(\mathcal{F}(\pi))$ as a co-augmentation:

$$C^\infty(P; \Lambda^q \mathcal{F}(0)^*)^G \xrightarrow{\eta} C^\infty(P; \Lambda^q \mathcal{F}(0)^*) \rightarrow C^\infty(P * G^{(1)}; \Lambda^q \mathcal{F}(1)^*) \rightarrow \dots \tag{21}$$

To define this, we consider the crossed product groupoid $P \rtimes G$. The action (19) of G on $\mathcal{F}(\pi) = \mathcal{F}(0)$ translates into the fact that $\mathcal{F}(0)$ (hence also $\Lambda^q \mathcal{F}(0)^*$) is a representation of $P \rtimes G$. Note also that $(P \rtimes G)^{(p)} = P * G^{(p)}$, and $\mathcal{F}(p)$, as a vector bundle, is the pull-back of $\mathcal{F}(0)$. Now, the co-augmentation η is the obvious inclusion, while the rest of (21) (i.e. the q^{th} row $C^{*,q}$) is defined as the complex $C_d^*(P \rtimes G; \Lambda^q \mathcal{F}(p)^*)$ computing the differentiable cohomology of $P \rtimes G$ with coefficients.

Since the properness of P as a G -space is equivalent to $P \rtimes G$ being proper, Proposition 1 implies that (21) is exact. Hence the inclusion $\eta : C_G^*(\mathcal{F}(\pi)) \rightarrow C$ induces isomorphisms:

$$\eta : H_G^*(\mathcal{F}(\pi)) \cong H^*(C) . \tag{22}$$

Combined with the inclusion $\epsilon : C_d^*(G) \rightarrow C$, this induces the desired map:

$$\Phi_P : H_d^*(G) \xrightarrow{\epsilon} H^*(C) \xrightarrow{\eta^{-1}} H_G^*(\mathcal{F}(\pi)) . \tag{23}$$

To prove that Φ_P is compatible with the products, note that $C^{p,q} \otimes C^{p',q'} \rightarrow C^{p+p',q+q'}$,

$$\begin{aligned} (\omega \cdot \eta)(x, g_1, \dots, g_{p+p'}) = \\ \omega(x, g_1, \dots, g_p) \wedge (g_1 \dots g_p)^{-1} \eta(xg_1 \dots g_p, g_{p+1}, \dots, g_{p+p'}) , \end{aligned}$$

defines a product on C , and ϵ and η are maps of DG algebras.

For the second part of the theorem, the spectral sequence of the double complex C , combined with (22), provides us with a spectral sequence

$$E_2^{p,q} = H^p(H^q(\mathcal{F}(*))) \implies H_G^{p+q}(\mathcal{F}(\pi)),$$

with $E_2^{p,0} = H_d^p(G)$, and with Φ_P as edge maps. Since each $\mathcal{F}(p)$ is a foliation defined by a submersion with homologically n -connected fibers, it follows from Theorem 2 (applied to the zero algebroid) that $E_2^{p,q} = 0$ for $1 \leq q \leq n$, hence the statement follows by the well known spectral-sequence arguments. \square

Remark 1 (connection with classifying spaces). This result is undoubtedly related to the classifying space BG of G [46], or, even better, to the classifying space for proper actions, familiar to the people working on the Baum-Connes conjecture. We discuss here the classifying space only. In general it is only defined up to homotopy, and this is important for choosing explicit models (depending on the context). Relevant for us is that it is the base space of a principal G -bundle $\sigma : EG \rightarrow BG$, whose moment map $\pi : EG \rightarrow G^{(0)}$ has contractible fibers. We say that G has a smooth classifying space BG if these choices can be made in the smooth category. Note that in this case, there is a natural (classifying?) Lie algebroid $\tilde{\mathfrak{g}}$ over BG , namely the Lie algebroid of the gauge groupoid (see Examples 1) of EG . Alternatively, $\mathcal{F}(\sigma) = \pi^*\mathfrak{g}$ naturally acts on $\mathcal{F}(\pi)$, and \mathfrak{g} is the quotient algebroid. We deduce the following result, which extends Haefliger's conjecture mentioned in the last part of our Examples 2.

Corollary 1. *Let G be a Lie groupoid with smooth classifying space BG , and let $\tilde{\mathfrak{g}}$ be the induced Lie algebroid over BG . Then there are isomorphisms compatible with the product structures:*

$$H_d^*(G) \cong H^*(\tilde{\mathfrak{g}}).$$

2.3. Application: relation between differentiable and algebroid cohomology

Let G be a Lie groupoid. Roughly speaking, Lie algebroid cocycles can be viewed as an infinitesimal version of groupoid cocycles. This translates into the existence of a map,

$$\Phi : H_d^p(G) \rightarrow H^p(\mathfrak{g}),$$

which we call *the Van Est map*. In the case of Lie groups it was constructed by Van Est [17, 18], and it was extended to Lie groupoids by Weinstein and Xu [50].

Explicitly, Φ is defined at the chain level by¹

$$\Phi(c)(X_1, \dots, X_p) = \sum_{\sigma \in S_p} \text{sign}(\sigma) R_{X_{\sigma(p)}} \dots R_{X_{\sigma(1)}}(c), \tag{24}$$

for all $c \in C_d^p(G)$, $X_1, \dots, X_p \in \Gamma(\mathfrak{g})$. Here, for $X \in \Gamma(\mathfrak{g})$ and $c \in C_d^p(G)$, $R_X(c) \in C_d^{p-1}(G)$ is given by

$$R_X(c)(g_2, \dots, g_p) = \frac{\partial c(-, g_2, \dots, g_p)}{\partial X}(\beta(g_2)), \tag{25}$$

the derivative at the identity of $c(-, g_2, \dots, g_p) : G(\beta(g_2), -) \rightarrow \mathbb{C}$, along the vector field on $G((\beta(g_2), -)$ induced by X .

This construction, together with the fact that it is an isomorphism in degree $p = 1$ provided G is α -simply connected, are part of the main results/tools of [50]. In the same paper it is conjectured that, if G has 2-connected α -fibers, then Φ is an isomorphism in degree $p = 2$. In this section we explain how the Van Est isomorphism of the previous section clarifies the connection between differentiable and algebroid cohomology (see the theorem below).

Let us first remark that there is a version of Φ in the presence of coefficients E : one only has to replace $c(-, g_2, \dots, g_p)$ in formula (25) by the function $G(\beta(g_2), -) \rightarrow E_{\beta(g_2)}$, $g \mapsto g^{-1}c(g, g_2, \dots, g_p)$.

Theorem 4. *Let G be an α -connected Lie groupoid, and let E be a representation of G . The formula (24) defines a map*

$$\Phi : H_d^p(G; E) \rightarrow H^p(\mathfrak{g}; E)$$

which is compatible with the product structures.

Moreover, if the α -fibers of G are homologically n -connected, then Φ is an isomorphism in degrees $p \leq n$, and is injective for $p = n + 1$.

Proof. We apply Theorem 3 to the right G -space $P = G^{(1)}$, with $\pi = \alpha$ as moment map, and the obvious action. Note that P is always proper as a G -space, and $C_G^*(\mathcal{F}(\pi); E)$ is isomorphic to $C_d^*(\mathfrak{g}; E)$ (since $\mathcal{F}(\pi) \cong \beta^*\mathfrak{g}$). Hence the only thing we have to prove is that the map Φ_P of Theorem 3 coincides with the map Φ (24) of the statement. We use the notations from the proof of Theorem 3, with $P = G^{(1)}$, and, as there, we also assume that the coefficients are trivial (as explained above, the difference with the general case is mainly notational). Since $\mathcal{F}(p) \cong \beta_{p+1}^*\mathfrak{g}$ (see (4)), C stands for the double complex $C^{p,q} = C^\infty(G^{(p+1)}; \Lambda^q(\beta^*\mathfrak{g}^*))$, and we view its elements as $C^\infty(G^{(0)})$ multilinear maps

$$\Gamma(\mathfrak{g}) \times \dots \times \Gamma(\mathfrak{g}) \ni (X_1, \dots, X_q) \mapsto c(X_1, \dots, X_q) \in C^\infty(G^{(p+1)}).$$

¹ As pointed out to me by Alan Weinstein, this is well defined (more precisely, it is tensorial) only if c is a normalized groupoid cocycle, i.e. c vanishes if one of the entries is a unit. So, in this section, all the terms which depend on strings of arrows of G , are assumed to satisfy the normalization condition. This is all right because normalized cocycles compute the same cohomology as non-normalized ones.

We need the explicit formulas for the horizontal boundary d^h (along q), and the vertical one d^v (along p) of C . First of all it is not difficult to see that

$$d^v(c)(X_1, \dots, X_q) = d'(c(X_1, \dots, X_q)) , \tag{26}$$

where

$$d' : C^\infty(G^{(p)}) \longrightarrow C^\infty(G^{(p+1)}),$$

$$d'(c)(g_1, \dots, g_{p+1}) = \sum_{i=1}^p (-1)^i c(g_1, \dots, g_i g_{i+1}, \dots, g_{p+1}) + (-1)^{p+1} c(g_1, \dots, g_p).$$

Secondly, since $\mathcal{F}(p) \cong \beta_{p+1}^* \mathfrak{g}$, we see that any section $X \in \Gamma(\mathfrak{g})$ induces a vector field \tilde{X} on $G^{(p+1)}$ which is tangent to $\mathcal{F}(p)$. Explicitly, the flow of \tilde{X} is given by:

$$\phi_{\tilde{X}}(g_1, \dots, g_{p+1}) = (\phi_X(t, g_1), g_2, \dots, g_{p+1}). \tag{27}$$

Since d^h is the boundary of the complex $C(\mathcal{F}(p))$, we see that the formula for d^h is the usual one:

$$d^h(c)(X_1, \dots, X_{q+1}) = \sum_{i < j} (-1)^{i+j-1} \omega([X_i, X_j], X_1, \dots, \hat{X}_i, \dots, \hat{X}_j, \dots, X_{q+1})$$

$$+ \sum_{i=1}^{q+1} (-1)^i L_{X_i}(\omega(X_1, \dots, \hat{X}_i, \dots, X_{q+1})), \tag{28}$$

with the warning that here L_X stands for the derivation on $C^\infty(G^{(p+1)})$ determined by \tilde{X} . Note also that, using these derivations, (25) is:

$$R_X(c) = L_X(c) \circ u, \quad \forall c \in C^\infty(G^{(p+1)}), \tag{29}$$

where

$$u : G^{(p)} \longrightarrow G^{(p+1)}, \quad u(g_1, \dots, g_p) = (\beta(g_1), g_1, \dots, g_p).$$

Looking at the construction (23) of Φ_P , to prove that it coincides (in cohomology) with Φ_i it suffices to construct a chain map $\tilde{\Phi} : C \longrightarrow C(\mathfrak{g})$ such that $\tilde{\Phi} \circ \epsilon = \Phi_P$, and $\eta \circ \tilde{\Phi} = id$. For $c \in C^{p,q}$, we define $\tilde{\Phi}(c) \in C^{p+q}(\mathfrak{g})$ by

$$\tilde{\Phi}(c)(X_1, \dots, X_{p+q})$$

$$= \sum_{\sigma \in S(p,q)} \text{sign}(\sigma) \Phi(c(X_{\sigma(1)}, \dots, X_{\sigma(q)} \circ u)(X_{\sigma(q+1)}, \dots, X_{\sigma(p+q)})),$$

where the sum is over all (p, q) -shuffles. E.g., for $c \in C^{p,1}$,

$$\tilde{\Phi}(c)(X_1, \dots, X_{p+1}) = \sum_i (-1)^{i+1} \Phi(c(X_i) \circ u)(X_1, \dots, \hat{X}_i, \dots, X_{p+1}), \tag{30}$$

and, for $c \in C^{p,2}$,

$$\tilde{\Phi}(c)(X_1, \dots, X_{p+2}) = \sum_{i < j} (-1)^{i+j+1} \Phi(c(X_i, X_j) \circ u)(X_1, \dots, \hat{X}_i, \dots, \hat{X}_j, \dots, X_{p+2}). \tag{31}$$

The only serious challenge is to prove that $\tilde{\Phi}$ defines a chain map from (the total complex of) C into $C(\mathfrak{g})$, i.e. we have to prove that

$$d(\tilde{\Phi}(c)) = (-1)^q \tilde{\Phi}(d^v(c)) + \tilde{\Phi}(d^h(c)), \quad \forall c \in C^{p,q}. \tag{32}$$

The proof of (32) is actually a combinatorial computation which is based only on the following properties of the map $\tilde{\Phi}$:

- (p1). $\tilde{\Phi} : C_d(G) \rightarrow C(\mathfrak{g})$ is a chain map;
- (p2). $\tilde{\Phi}(c) = 0$ if $c(g_1, \dots, g_p)$ does not depend on the variable g_1 . Note that, together with (p1) this implies that $d\tilde{\Phi}(c \circ u) = \tilde{\Phi}(d'(c) \circ u) - \tilde{\Phi}(c)$ for all $c \in C_d(G)$;
- (p3). for all $c \in C^\infty(G^{(p+1)})$ one has:

$$\sum_i (-1)^{i+1} \tilde{\Phi}(R_{X_i}(c))(X_1, \dots, \hat{X}_i, \dots, X_{p+1}) = \tilde{\Phi}(c)(X_1, \dots, X_{p+1}).$$

All these properties are easy to check (and have been remarked also in [50]). Since the proof of (32) for $q = 1$ contains all the intricacies of the general case, to simplify the exposition we restrict ourselves to this particular case. Hence, let $c \in C^{p,1}$. Then $d(\tilde{\Phi}(c))(X_1, \dots, X_{p+2})$ equals to

$$\begin{aligned} & \sum_{i < j} (-1)^{i+j+1} \tilde{\Phi}(c)([X_i, X_j], X_1, \dots, \hat{X}_i, \dots, \hat{X}_j, \dots, X_{p+2}) \\ & + \sum_i L_{X_i}(\tilde{\Phi}(c)(X_1, \dots, \hat{X}_i, \dots, X_{p+2})), \end{aligned}$$

and, by the definition of $\tilde{\Phi}$ (see the particular formula (30) above), this is

$$\begin{aligned} & \sum_{i < j} (-1)^{i+j+1} \tilde{\Phi}(c([X_i, X_j] \circ u))(X_1, \dots, \hat{X}_i, \dots, \hat{X}_j, \dots, X_{p+2}) \\ & + \sum_{r < i < j} (-1)^{i+j+1} (-1)^r \tilde{\Phi}(c(X_r) \circ u)([X_i, X_j], X_1, \dots, \hat{X}_r, \dots, \hat{X}_i, \dots, \hat{X}_j, \dots, X_{p+2}) \\ & + \sum_{i < r < j} (-1)^{i+j+1} (-1)^{r+1} \tilde{\Phi}(c(X_r) \circ u)([X_i, X_j], X_1, \dots, \hat{X}_i, \dots, \hat{X}_r, \dots, \hat{X}_j, \dots, X_{p+2}) \\ & + \sum_{i < j < r} (-1)^{i+j+1} (-1)^r \tilde{\Phi}(c(X_r) \circ u)([X_i, X_j], X_1, \dots, \hat{X}_i, \dots, \hat{X}_j, \dots, \hat{X}_r, \dots, X_{p+2}) \\ & + \sum_{r < i} (-1)^i (-1)^{r+1} L_{X_i}(\tilde{\Phi}(c(X_r) \circ u))(X_1, \dots, \hat{X}_r, \dots, \hat{X}_i, \dots, X_{p+2}) \\ & + \sum_{i < r} (-1)^i (-1)^r L_{X_i}(\tilde{\Phi}(c(X_r) \circ u))(X_1, \dots, \hat{X}_i, \dots, \hat{X}_r, \dots, X_{p+2}). \end{aligned}$$

Now, fixing r , by the definition of the differential of $C(\mathfrak{g})$, the sum (over i) of the last five terms equals $(-1)^r d(\tilde{\Phi}(c(X_r) \circ u))(X_1, \dots, \hat{X}_i, \dots, X_{p+2})$, which, by (p2) and (26), is $(-1)^r \tilde{\Phi}(d^v(c)(X_r) \circ u) + (-1)^{r+1} \tilde{\Phi}(c(X_r))$ applied to $(X_1, \dots, \hat{X}_r,$

\dots, X_{p+2}). Hence our big sum equals to

$$\sum_{i < j} (-1)^{i+j+1} \Phi(c([X_i, X_j] \circ u))(X_1, \dots, \hat{X}_i, \dots, \hat{X}_j, \dots, X_{p+2}) \tag{33}$$

$$+ \sum_r (-1)^{r+1} \Phi(c(X_r))(X_1, \dots, \hat{X}_r, \dots, X_{p+2}) \tag{34}$$

$$+ \sum_r (-1)^r \Phi(d^v(c)(X_r) \circ u)(X_1, \dots, \hat{X}_r, \dots, X_{p+2}).$$

Since the last term is $-\tilde{\Phi}(d^v(c))(X_1, \dots, X_{p+2})$ (cf. (p3) above), we are left with showing the connection of the terms (33) and (34) with the horizontal boundary of C . Let us compute $\tilde{\Phi}(d^h(c))(X_1, \dots, X_{p+2})$. By definition (see (31) above), it is

$$\sum_{i < j} (-1)^{i+j+1} \Phi(d^h(c)(X_i, X_j) \circ u)(X_1, \dots, \hat{X}_i, \dots, \hat{X}_j, \dots, X_{p+2}).$$

By the formulas (28) and (29), this is equal to

$$\begin{aligned} &= \sum_{i < j} (-1)^{i+j+1} \Phi(c([X_i, X_j] \circ u))(X_1, \dots, \hat{X}_i, \dots, \hat{X}_j, \dots, X_{p+2}) \\ &- \sum_{i < j} (-1)^{i+j+1} \Phi(R_{X_i}(c(X_j)))(X_1, \dots, \hat{X}_i, \dots, \hat{X}_j, \dots, X_{p+2}) \end{aligned} \tag{35}$$

$$+ \sum_{i < j} (-1)^{i+j+1} \Phi(R_{X_j}(c(X_i)))(X_1, \dots, \hat{X}_i, \dots, \hat{X}_j, \dots, X_{p+2}). \tag{36}$$

Replacing the pair (i, j) by (j, i) in (36), we see that the sum of (35) and (36) is the sum over j of

$$\begin{aligned} &(-1)^j \left\{ \sum_{i < j} (-1)^i \Phi(R_{X_i}(c(X_j)))(X_1, \dots, \hat{X}_i, \dots, \hat{X}_j, \dots, X_{p+2}) \right. \\ &\left. + \sum_{i > j} (-1)^{i+1} \Phi(R_{X_i}(c(X_j)))(X_1, \dots, \hat{X}_j, \dots, \hat{X}_i, \dots, X_{p+2}) \right\}. \end{aligned}$$

By (p3) this is equal to

$$\sum_j (-1)^{j+1} \Phi(c(X_j))(X_1, \dots, \hat{X}_j, \dots, X_{p+2}),$$

hence $\tilde{\Phi}(d^h(c))(X_1, \dots, X_{p+2})$ is precisely the sum of the two expressions (33) and (34). In conclusion, we get the desired relation $d(\tilde{\Phi}(c)) = \tilde{\Phi}(d^h(c)) - \tilde{\Phi}(d^v(c))$. \square

Remark 2. The formulas (27) and (29) in the previous proof show that the map Φ can be expressed in terms of the flows (see subsection 1.3) of sections of \mathfrak{g} . More precisely, for all $X_1, \dots, X_p \in \Gamma(\mathfrak{g})$, and $c \in C_d^p(G)$, $R_{X_p} \dots R_{X_1}(c)(x)$ equals to the derivative at $t_1 = \dots = t_p = 0$ of

$$\begin{aligned} &c(\phi_{X_1}(t_1, \beta_{X_2}(t_2, \beta_{X_3}(t_3, \dots, \beta_{X_p}(t_p, x) \dots))) , \\ &\quad \phi_{X_2}(t_2, \beta_{X_3}(t_3, \dots, \beta_{X_p}(t_p, x) \dots)) , \\ &\quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot , \\ &\quad \phi_{X_p}(t_p, x) \end{aligned}$$

In the presence of coefficients E , one has to transport the previous element into the fiber E_x , i.e. to multiply it by the element

$$\phi_{X_1}(t_1, \phi_{X_2}(t_2, \phi_{X_3}(t_3, \dots, \phi_{X_p}(t_p, x) \dots)))^{-1}.$$

Remark 3. Note that, as in the case of classical “van-Est isomorphisms” [17, 18, 19], it is rather the method that gives us the maximal information. For instance, the previous double complex induces a spectral sequence which converges to the algebroid cohomology, and the theorem above is just a simple consequence. By the usual arguments of algebraic topology, if the fibers of G are (homological) $n + 1$ -spheres we obtain a Gysin-type long exact sequence relating differentiable and algebroid cohomology. Note also that the lower non-trivial part of the spectral sequence provides us with a description of the image of the Van Est map in degree $n + 1$. To explain this, we consider $n + 1$ α -loops in G i.e. smooth maps $\gamma : S^{n+1} \rightarrow G$ with the property that $\alpha \circ \gamma = x$ is constant. For any such γ we have a map $\int_\gamma : H^{n+1}(\mathfrak{g}) \rightarrow \mathbb{R}$, $[\omega] \mapsto \int_{S^{n+1}} \gamma^* \omega|_L$, where $L = G(x, -)$. Note that \int_γ depends only on the homotopy class of γ inside L . In particular, if the homotopy class of γ is an element of finite order, then $\int_\gamma = 0$. The conclusion is:

Corollary 2. *If the α -fibers of G are (homologically) n -connected, then $\omega \in H^{n+1}(\mathfrak{g})$ is in the image of the Van Est map if and only if $\int_\gamma \omega = 0$ for all $n + 1$ α -loops γ .*

Remark 4 (compact supports). In relation with the cyclic cohomology of the convolution algebra, it is relevant to have a compactly supported version of differentiable cohomology and of our results. We prefer to call this cohomology with compact supports a homology theory, and denote it by $H_*^d(G)$ instead of $H_{cpt,d}^*(G)$; this is in agreement also with the homology theory described in [12], which we recover when G is étale. The definition of $H_*^d(G)$, in analogy with the definition of the convolution product [45], depends on the choice of a smooth Haar system λ for G . For the definition, see the proof of our Proposition 1. The (chain) complex $C_*^d(G)$ defining this homology consists of the differentiable cochains with

compact supports, while the differential is given by

$$(dc)(g_1, \dots, g_p) = \int c(a^{-1}, g_1, \dots, g_p) d\lambda^{\beta(g_1)}(a) \tag{37}$$

$$+ \sum_{i=1}^p (-1)^i \int c(g_1, \dots, g_i a, a^{-1}, g_{i+1}, \dots, g_p) d\lambda^{\alpha(g_i)}(a) \tag{38}$$

$$+ (-1)^{p+1} \int c(g_1, \dots, g_p, a) d\lambda^{\alpha(g_p)}(a). \tag{39}$$

A compactly version of our proofs shows that:

1. $H_*^d(G)$ is Morita invariant. In particular (compare to the similar statement for convolution algebras [40]), it does not depend on the choice of the smooth Haar system λ .

2. Denote by q the dimension of \mathfrak{g} , and by $H_{cpt}^*(\mathfrak{g})$ the algebroid cohomology with compact supports. Assume we are in the orientable case (in general, some twisting in the algebroid cohomology is necessary). If G has homologically n -connected fibers, then one has isomorphisms $H_k^d(G) \cong H_{cpt}^{q-k}(G)$ for all $0 \leq k \leq n$.

2.4. Application: an integrability result

As an application of Theorem 4, we show the following integrability result. In the case of Lie algebras this result is precisely the argument given by Van Est [17] for a short proof of Lie’s third theorem. An immediate consequence will be a more conceptual proof and a slight improvement of Dazord–Hector’s integrability criterion for Poisson manifolds (this will be explained in the last section).

Theorem 5. *Let*

$$0 \longrightarrow \mathfrak{l} \xrightarrow{i} \mathfrak{h} \xrightarrow{\pi} \mathfrak{g} \longrightarrow 0 \tag{40}$$

be an exact sequence of Lie algebroids, with \mathfrak{l} abelian. If \mathfrak{g} admits a Hausdorff integration whose α -fibers are simply connected and have vanishing second cohomology groups, then \mathfrak{h} is integrable (and the integration can be chosen to be Hausdorff and α -simply connected).

Proof. We need the following remarks:

1. Given a representation E of a Lie algebroid \mathfrak{g} over M , and $\omega \in C^2(\mathfrak{g}; E)$ closed, one can form a twisted semi-direct product Lie algebroid $\mathfrak{g} \times_{\omega} E$. As a vector bundle it is $\mathfrak{g} \oplus E$, with the anchor $(X, V) \mapsto \rho(X)$, and with the bracket

$$[(X, V), (Y, W)] = ([X, Y], L_X(W) - L_Y(V) + \omega(X, Y)) ,$$

for $X, Y \in \Gamma(\mathfrak{g}), V, W \in \Gamma(E)$. Moreover, the isomorphism class of $\mathfrak{g} \times_{\omega} E$ depends only on the cohomology class $[\omega] \in H^2(\mathfrak{g}; E)$. In the trivial case ($\omega = 0$), one

obtains the usual semi-direct product $\mathfrak{g} \ltimes E$. These remarks are well-known [32] and follow by direct computation.

2. Similarly, given a representation E of a Lie groupoid G over M , and $c \in C_d^2(G; E)$ closed and normalized, one forms the groupoid $G \times_c E$ over M , whose space of objects is $G^{(1)} \times_{G^{(0)}} E$, with the product

$$(g_1, v_1)(g_2, v_2) = (g_1 g_2, g_1^{-1} \cdot v_1 + v_2 + (g_1 g_2)^{-1} \cdot c(g_1, g_2)) .$$

Moreover, $Lie(G \times_c E) \cong \mathfrak{g} \ltimes_\omega E$, where $\omega = \Phi(c)$. Since this is obvious as an isomorphism of vector bundles, the more serious task is to identify the bracket of $Lie(G \times_c E)$. For this, one notes that the flows $\phi_{(X,V)}$ ($X \in \Gamma(\mathfrak{g})$, $V \in \Gamma(E)$) for $G \times_c E$ are given by

$$\phi_{X,V}(t, x) = (\phi_X(t, x), tV(x)), \quad x \in M ,$$

and then one uses the formula (8) for the Lie bracket in $Lie(G \times_c E)$, the formula (9) for the action of \mathfrak{g} on E , and the formula described in Remark 2 for the map Φ .

3. Given an extension (40) as in the statement, there is a canonical action of \mathfrak{g} on \mathfrak{l} , and a canonical cohomology class $[\omega] \in H^2(\mathfrak{g}; \mathfrak{l})$ such that $\mathfrak{h} \cong \mathfrak{g} \ltimes_\omega \mathfrak{l}$. They are determined by the formulas

$$i(L_X(V)) = [\sigma(X), i(V)], \quad i(\omega(X, Y)) = \sigma([X, Y]) - [\sigma(X), \sigma(Y)] ,$$

for $X, Y \in \Gamma(\mathfrak{g}), V \in \Gamma(\mathfrak{h})$, where $\sigma : \mathfrak{g} \rightarrow \mathfrak{h}$ is a/any linear splitting of π . This is an easy computation, whose conclusion is the well known correspondence [32] between 2-cohomology classes $[\omega] \in H^2(\mathfrak{g}; \mathfrak{l})$ and extensions (40).

The proof of the theorem is quite obvious now: let G be the integration of \mathfrak{g} whose existence is part of the hypothesis. Then, the canonical action of \mathfrak{g} on \mathfrak{l} (cf. 3. above) comes from an action of G on \mathfrak{l} since G is α -simply connected (see subsection 1.4). By theorem 4, the canonical 2-cohomology class $\omega \in H^2(\mathfrak{g}; \mathfrak{l})$ (cf. 3. above) is of type $\omega = \Phi(c)$ for some $c \in H_d^2(G; \mathfrak{l})$. Then, using 2. above, we see that $H = G \times_c \mathfrak{l}$ is a (Hausdorff) integration of \mathfrak{h} . \square

Remark 5. Actually we have proven a bit more than stated: given an extension (40), it defines a cohomology class in $\omega \in H^2(\mathfrak{g}; \mathfrak{l})$, and, if this class is integrable (i.e. in the image of the Van Est map), then \mathfrak{h} is integrable. As explained in the introduction, this theorem immediately implies Lie’s third theorem (see also section 14 in [17]). Essential for this is that simply connected Lie groups have vanishing second cohomology groups, and that we can use the adjoint representation. For Lie groupoids these both fail. Note that the most difficult problem to overcome is the non-existence of the adjoint representation for general Lie algebroids. However, there are no such difficulties in the case of Lie algebra bundles (the LAB’s of [32]), or, more generally, in the case of bundles of Lie algebras with

regular center (i.e. with the property that the centers of the Lie algebra fibers fit into a vector bundle). The resulting integrability results are particular cases of Douady–Lazard’s theorem [15].

3. Characteristic classes in algebroid cohomology

The aim of this section is to find the characteristic invariants living in algebroid cohomology, as well as their relation to the Van Est map. As we have already mentioned, many examples of Lie algebroids arise naturally and, even if they are integrable, the integrating groupoids may be difficult to visualise (the best examples this remark applies to are probably the Lie algebroids associated to Poisson manifolds, but this type of phenomenon occurs even in the case of foliations). For this reason we insist on working at the algebroid level.

Asking for characteristic invariants living in algebroid cohomology, there is an obvious (and naive) construction. Using the composition with the anchor, $\rho_* : H^*(M) \longrightarrow H^*(\mathfrak{g})$, we define the \mathfrak{g} -Chern classes of a vector bundle E over M by

$$Ch_k^{\mathfrak{g}}(E) := \rho_*(Ch_k(E)) \in H^{2k}(\mathfrak{g}), \quad k \geq 0.$$

In the case of foliations, these characteristic classes were studied by Moore Schuchet [39] under the name of the foliated Chern classes. They also appear in the geometry of Poisson manifolds P , when E is e.g. a co-foliation on P [48]. In subsection 3.2 we will prove that $Ch_k^{\mathfrak{g}}(E)$ can be computed using \mathfrak{g} -connections on E [20]; this will be done in the proof of the following theorem, which shows that these classes can also be viewed as obstructions to the existence of infinitesimal actions of \mathfrak{g} on E .

Theorem 6. *For any representation E of \mathfrak{g} , the Chern classes $Ch_k^{\mathfrak{g}}(E) \in H^{2k}(\mathfrak{g})$ vanish for $k \geq 1$.*

According to the general principle that a vanishing result for certain characteristic classes is the origin of new (secondary) characteristic classes which are made out of the transgression of the vanishing ones, the previous proposition rises the question of finding the non-trivial cohomological invariants of representations of \mathfrak{g} .

In the next subsection we will show in an explicit fashion how a first such class arises naturally; the complete description of the secondary classes (and the proof of the theorem above) will be given in the subsection 3.2. In 3.3 we will describe the relation with the Van Est map.

Warning. So far, the choice of the basic field (real or complex numbers) was irrelevant. From now on we use the notations $\text{Rep}_{\mathbb{R}}(\mathfrak{g})$ and $\text{Rep}_{\mathbb{C}}(\mathfrak{g})$ to distinguish between real/complex representations. Also we consider *only cohomology with real coefficients* (hence $H^*(\mathfrak{g})$ will always stand for $H^*(\mathfrak{g}; \mathbb{R})$).

3.1. The first characteristic class u_1

We now describe, in a direct manner, the first cohomology class $u_1(E) \in H^1(\mathfrak{g})$ of a representation E of the Lie algebroid \mathfrak{g} . Denote by M the base manifold. We consider the real/complex cases separately.

The real case. Let $E \in \text{Rep}_{\mathbb{R}}(\mathfrak{g})$. We first assume that E , as a vector bundle over M , is trivializable, and let $e = \{e_1, \dots, e_n\}$ be a frame of E . Then the equation:

$$L_X(e_j) = \sum \omega_j^i(X)e_i, \quad X \in \Gamma(\mathfrak{g})$$

shows that the action of \mathfrak{g} on E is uniquely determined by a matrix:

$$\omega_e = (\omega_j^i)_{1 \leq i, j \leq n} \in M_n(C^1(\mathfrak{g}))$$

satisfying the flatness condition

$$d\omega_e = \omega_e \wedge \omega_e = \frac{1}{2}[\omega_e, \omega_e].$$

The last relation implies that

$$\text{Tr}(\omega_e) \in C^1(\mathfrak{g})$$

is closed. The same happens with the forms

$$\text{Tr}(\underbrace{\omega_e \wedge \dots \wedge \omega_e}_{2k-1}) \in C^{2k-1}(\mathfrak{g}), \tag{41}$$

but at these classes we will look in the next subsection.

If $f = \{f_1, \dots, f_n\}$ is another frame, and $A = (a_j^i) \in M_n(C^\infty(M))$ is the change of coordinates matrix, i.e. $e_j = \sum a_j^i f_i$, one can easily see that the matrix corresponding to f is

$$\omega_f = A\omega_e A^{-1} + (dA)A^{-1}. \tag{42}$$

This implies

$$\text{Tr}(\omega_f) = \text{Tr}(\omega_e) + d(\log |\det A|),$$

hence the class:

$$u_1(E) := [\text{Tr}(\omega_e)] \in H^1(\mathfrak{g}) \tag{43}$$

does not depend on the choice of the trivialisation.

We now return to the general case, where E is not necessarily trivializable. We choose a covering $\mathcal{U} = \{U_\alpha\}$ of domains of trivialization of E , and let

$$h_{\alpha, \beta} : U_\alpha \cap U_\beta \longrightarrow GL_n$$

be the transition functions of E . The previous construction provides us with 1-forms of the restrictions of \mathfrak{g} to U_α 's:

$$u(\alpha) = \text{Tr}(\omega_\alpha) \in C^1(U_\alpha; \mathfrak{g}),$$

and with functions

$$u(\alpha, \beta) = \log |\det(h(\alpha, \beta))| \in C^0(U_\alpha \cap U_\beta; \mathfrak{g})$$

satisfying:

$$\begin{aligned} d(u(\alpha)) &= 0 \text{ on } U_\alpha, \\ d(u(\alpha, \beta)) &= u(\alpha) - u(\beta) \text{ on } U_\alpha \cap U_\beta, \\ u(\alpha, \beta) - u(\alpha, \gamma) + u(\beta, \gamma) &= 0 \text{ on } U_\alpha \cap U_\beta \cap U_\gamma, \end{aligned}$$

The last relation follows from the cocycle relations satisfied by the transition functions. These relations are precisely the relations defining a closed cocycle u in the Čech double complex $\check{C}^*(\mathcal{U}; C^*(\mathfrak{g}))$. By a Mayer–Vietoris argument (cf. e.g. [5]), one has exact sequences

$$0 \longrightarrow C^p(\mathfrak{g}) \xrightarrow{r_{\mathcal{U}}} \check{C}^0(\mathcal{U}; C^p(\mathfrak{g})) \xrightarrow{\delta} \check{C}^1(\mathcal{U}; C^p(\mathfrak{g})) \xrightarrow{\delta} \dots$$

where δ is the Čech boundary, and $r_{\mathcal{U}}$ is the obvious restriction to opens $U \in \mathcal{U}$. Hence the map $r_{\mathcal{U}}$ can be viewed as a map from $C^*(\mathfrak{g})$ into (the total complex of) $\check{C}^*(\mathcal{U}; C^*(\mathfrak{g}))$, which induces an isomorphism in cohomology, and we define

$$u_1(E) = r_{\mathcal{U}}^{-1}([u]) \in H^1(\mathfrak{g}).$$

By the same arguments as in the trivialisable case:

Proposition 2. *Given a representation E of a Lie algebroid \mathfrak{g} , the previously constructed class $u_1(E) \in H^1(\mathfrak{g})$ does not depend on the choice of the local trivialisations, and, when E is trivialisable as a vector bundle, it is given by the formula (43).*

The complex case. Assume now that $E \in \text{Rep}_{\mathbb{C}}(\mathfrak{g})$. We can simply define $u_1(E) = \frac{1}{2}u_1(E_{\mathbb{R}})$, where $E_{\mathbb{R}}$ is the real representation underlying E . Although this is correct, it is quite instructive to try to imitate the real case. As above, the choice of a trivialization e (over \mathbb{C}) for E defines a matrix ω_e , and

$$\text{Tr}(\omega_e) \in C^1(\mathfrak{g}; \mathbb{C})$$

will be a closed cocycle. However, simple examples show that it is only $\text{Tr}(\text{Re}(\omega_e))$ that is invariant under the change of trivialisations. Indeed, the analogue of (42) gives

$$\text{Tr}(\omega_f) - \text{Tr}(\omega_e) = \frac{\alpha d\alpha + \beta d\beta}{\alpha^2 + \beta^2} + i \frac{\alpha d\beta - \beta d\alpha}{\alpha^2 + \beta^2},$$

where $\alpha + i\beta = \det(A)$. While $(\alpha d\alpha + \beta d\beta)/(\alpha^2 + \beta^2)$ is $d(\log|\det(A)|)$,

$$\frac{\alpha d\beta - \beta d\alpha}{\alpha^2 + \beta^2} \tag{44}$$

is not always exact. Since $\text{Tr}(\text{Re}(\omega_f)) = \text{Tr}(\text{Re}(\omega_e)) + d(\log|\det A|)$ we can proceed exactly as in the real case (with $\text{Tr}(\omega_e)$ replaced by $\text{Tr}(\text{Re}(\omega_e))$) and define the class $u_1(E) \in H^1(\mathfrak{g})$. It coincides with $\frac{1}{2}u_1(E_{\mathbb{R}})$.

Note that what the complex case really teaches us is that, if one wants to fully use the closed forms $Tr(\omega_e)$, there is an obstruction to the independence on e , obstruction which comes from the non-exactness of (44). It is worth to point out that (44) gives the volume form on $S^1 = U(1)$. Although this type of phenomenon has not been seen in the real case above, it will be present in higher dimensions both for real and complex representations.

Examples 6. In the case of 1-dimensional representations L , then our $u_1(L)$ coincides with the characteristic class θ_L introduced in [20]. The modular class of \mathfrak{g} is defined as $u_1(Q_{\mathfrak{g}})$, where $Q_{\mathfrak{g}} = \Lambda^{top} \mathfrak{g} \otimes \Lambda^{top} T^*M$ is the canonical line bundle of \mathfrak{g} . When applied to the Lie algebroid associated to a Poisson manifold P , one obtains (up to a constant) the modular class of P . For more details see [20], and also our last section.

Let us now look at a simple example which shows the non-triviality of u_1 . Let $X \in \mathcal{X}(M)$ be a vector field on the manifold M . It induces a Lie algebroid \mathfrak{g}_X over M : as a vector bundle it is just $M \times \mathbb{R}$, ρ is the multiplication by X , while the Lie bracket on $\Gamma(\mathfrak{g}_X) = C^\infty(M)$ is $[f, g] = fX(g) - X(f)g$. For any zero x of X , the evaluation at x defines a map $ev_x : H^1(\mathfrak{g}_X) \rightarrow \mathbb{C}$. The cotangent bundle T^*M is a representation of \mathfrak{g}_X ; a local computation shows that $ev_x(u_1(T^*(M))) = \sum_i \frac{\partial X^i}{\partial x^i}(x)$, where (x^1, \dots, x^n) is a/an any system of local coordinates around x .

3.2. The higher characteristic classes u_{2k-1}

The key of finding all the higher cohomological invariants of representations is a better understanding of the notion of representation, in terms of frame bundles (see Corollary 3 below). This is analogous to the correspondence between connections on a vector bundle over a manifold, and connections on the associated principal GL_n (frame) bundle. To any $E \in \text{Rep}(\mathfrak{g})$ we will associate certain classes $u_{2k-1}(E) \in H^{2k-1}(\mathfrak{g})$ which are non-trivial only when $1 \leq k \leq \dim(E)$, and which for real representation vanish for even k 's. To get a feeling about the final result, I mention here that the forms defining these classes are just some ‘‘corrections’’ of (41) (see also Examples 7).

Explicit approach (sketch). Let E be a (complex or real) representation of \mathfrak{g} . As in the previous subsection, we first assume that E has a trivialization e . We have noticed that, together with $Tr(\omega_e)$, we also have the closed forms (41). Of course, they appear as the natural candidates for the higher cohomological invariants of E . However, as hinted by the complex case above, the resulting classes depend on the trivialization e , hence they cannot be globalized. Instead, we have to ‘‘correct’’ these classes (41) and consider:

$$Tr(\underbrace{\theta_e \wedge \dots \wedge \theta_e}_{2k-1}) \in C^{2k-1}(\mathfrak{g}), \quad \theta_e = (\omega_e + \omega_e^*)/2 \tag{45}$$

(where $\omega_e^* = (\overline{\omega_e})^t$). The full understanding of this choice, and of the fact that these are all geometric classes one can construct, lies in the computation of the differentiable cohomology of GL_n , and the global understanding of representations in terms of frame bundles. This will be done below. We leave for the reader to show that the previous classes are indeed closed, and that in the real case they vanish if i is even.

For the sake of explicit formulas, I mention here a global expression of these classes (see also [2]). Hence, let E be any representation (real or complex) of \mathfrak{g} . Denote by ∇ the action of \mathfrak{g} on E , and by ∇^* be the dual action of \mathfrak{g} on E^* . Let h be a metric on E . Using the isomorphism $E \cong E^*$ induced by h , we transport ∇^* to a new action of \mathfrak{g} on E , denoted ∇^h . Then $\theta(E, h) := (\nabla - \nabla^h)/2$ is in $C^1(\mathfrak{g}; \text{End}(E))$, and, up to a constant, the classes $u_{2k-1}(E)$ will be given by (45) with θ_e replaced by $\theta(E, h)$. Alternatively, one can use a transgression (à la Chern–Weil) construction for (∇, ∇^h) . The resulting cohomology classes will be independent of the choice of the metric. We now turn to the promised approach, in terms of frame bundles.

Global approach. To obtain all the characteristic classes at once, we restrict to the complex case, and, for E real, we will define $u_{2k-1}(E) = u_{2k-1}(E_{\mathbb{C}})$, where $E_{\mathbb{C}}$ is the complexification of E . Hence let E be an n -dimensional complex representation of \mathfrak{g} . Denote by $\pi : P \rightarrow M$ the frame bundle of E . We have already seen that, fixing a frame $\{e_1, \dots, e_n\}$ for E , the action of \mathfrak{g} on E is uniquely determined by a matrix $\omega_e \in C^1(\mathfrak{g}) \otimes gl_n$ satisfying $d\omega_e = \frac{1}{2}[\omega_e, \omega_e]$. On the other hand, the basic properties (10), (11) of an action show (as in the case of connections on vector bundles) that the expression $L_X(s)(x)$, for $x \in M$, depends only on X_x and on the restriction of s to an integral curve of $\rho(X) \in \mathcal{X}(M)$ through x . Combining the previous two remarks we see that, for any $e(0) = \{e_1(0), \dots, e_n(0)\} \in P$ a frame of E_x , any $X \in \mathfrak{g}_x$, and any tangent vector $V \in T_{e(0)}P$ defined by a curve of frames $e : (-\epsilon, \epsilon) \rightarrow P$ around $e(0)$ such that

$$\rho(X) = (d\pi)_p(V), \tag{46}$$

one has an (unique) associated matrix $\omega_j^i = \omega_j^i(X, V) \in gl_n$ such that $L_X(e_j) = \sum \omega_j^i e_i$. Now, (46) is precisely the relation defining the pullback algebroid $\pi^!(\mathfrak{g})$ (see Examples 5). Hence the previous construction provides us with an element

$$\omega = \omega_E \in C^1(\pi^!\mathfrak{g}) \otimes gl_n. \tag{47}$$

To understand the special features of ω we use the canonical Lie algebra map

$$gl_n \rightarrow \Gamma(\pi^!\mathfrak{g}), \quad v \mapsto v^\# = (0, v_P). \tag{48}$$

Here $v_P \in \mathcal{X}(P)$ is the transport of v to P ; it comes from the differential (at the identity matrix)

$$j_p : gl_n \rightarrow T_pP \tag{49}$$

of the multiplication map $GL_n \rightarrow P, g \mapsto p \cdot g$. Note that, since the inclusion (49) maps gl_n isomorphically into the space of vertical vector fields on P (i.e. killed by the differential of π), v^\sharp does indeed define an element in $\Gamma(\pi^! \mathfrak{g})$. Now, the Cartan calculus on $\pi^! \mathfrak{g}$ (cf. 1.4), together with the Lie algebra map (48), endows the DG algebra $C(\pi^! \mathfrak{g})$ with Lie derivatives (which are derivations of degree 0) and interior products (which are derivations of degree 1),

$$L_v : C(\pi^! \mathfrak{g}) \rightarrow C(\pi^! \mathfrak{g}), \quad i_v : C(\pi^! \mathfrak{g}) \rightarrow C^{*-1}(\pi^! \mathfrak{g}),$$

linear on $v \in gl_n$, and which satisfy the Cartan relations (14)–(17). The Lie derivatives can be viewed also as the infinitesimal version of the canonical action of GL_n on $C(\pi^! \mathfrak{g})$. In the standard terminology which originates in Cartan’s interpretation of connections (see [30] and the references therein), $C(\pi^! \mathfrak{g})$ is a gl_n -DG algebra. The main properties of the 1-form (47) are:

- (i) $i_v(\omega) = v$ for all $v \in gl_n$,
- (ii) ω is GL_n -invariant,
- (iii) $d\omega = \frac{1}{2}[\omega, \omega]$.

(i.e., in the terminology of [30] again, ω is a flat connection for the gl_n -DG algebra $C(\pi^! \mathfrak{g})$). We can interpret (47) as a map $gl_n^* \rightarrow C^1(\pi^! \mathfrak{g})$, which can be uniquely extended to a map of algebras

$$k_E : C^*(gl_n) \rightarrow C^*(\pi^! \mathfrak{g}). \tag{50}$$

It is easy to see that the basic properties of ω translate into:

- (i') k_E is compatible with the interior products $i_v, v \in gl_n$,
- (ii') k_E is compatible with the Lie derivatives $L_v, v \in gl_n$,
- (iii') k_E is compatible with the differentials.

(This is the standard passing from a flat connection 1-form ω to a map of gl_n -DG algebras.) Moreover, we can also go backwards, hence our discussion can be summarized into:

Corollary 3. *Let \mathfrak{g} be a Lie algebroid, let E be a vector bundle over the base manifold M of \mathfrak{g} , and let $\pi : P \rightarrow M$ be the associated principal GL_n -bundle of E . Then there is a one to one correspondence between:*

- (1) a pairing $\Gamma(\mathfrak{g}) \times \Gamma(E) \rightarrow \Gamma(E)$ which makes E into a representation of \mathfrak{g} ;
- (2) a 1-form $\omega \in C^1(\pi^! \mathfrak{g}) \otimes gl_n$ satisfying (i)–(iii) above;
- (3) a map $k : C^*(gl_n) \rightarrow C^*(\pi^! \mathfrak{g})$ of DG algebras, satisfying (i')–(iii') above.

Now, given our representation E , k_E induces a map at the level of $U(n)$ -basic elements, i.e. elements which are $U(n)$ -invariant, and are killed by all i_v ’s with $v \in u_n$,

$$k_E : C^*(gl_n)_{U(n)\text{-basic}} \rightarrow C^*(\pi^! \mathfrak{g})_{U(n)\text{-basic}} . \tag{51}$$

The reason for passing to $U(n)$ -basic elements is that we can get down from $\pi^! \mathfrak{g}$ over P to \mathfrak{g} over M . Indeed, the right hand side is isomorphic to $C^*(\pi_0^! \mathfrak{g})$, where

$\pi_0 : P_0 = P/U(n) \longrightarrow M$ is the obvious projection. Its fibers are contractible, hence, by Theorem 2, it induces isomorphisms

$$\pi_0^* : H^*(\mathfrak{g}) \xrightarrow{\sim} H^*(\pi_0^! \mathfrak{g}).$$

On the other hand, the right hand side of (51) is precisely the complex computing the relative Lie algebra cohomology $H^*(gl_n, U(n))$. Recall (see e.g. [30]) that this cohomology is the exterior algebra on n generators $u_1, u_3, \dots, u_{2n-1}$ of degrees $deg(u_{2k-1}) = 2k - 1$. Hence, from (51) we get a map in cohomology

$$k_E : \Lambda^*(u_1, u_3, \dots, u_{2n-1}) \cong H^*(gl_n, U(n)) \longrightarrow H^*(\mathfrak{g}). \tag{52}$$

Definition 1. Define the characteristic classes of the n -dimensional representation E of the Lie algebroid \mathfrak{g} as:

$$u_{2k-1}(E) := k_E(u_{2k-1}) \in H^{2k-1}(\mathfrak{g}), \quad 1 \leq i \leq n.$$

Main properties. The main properties that the u_{2k-1} 's satisfy are:

- (i) $u_{2k-1}(E \oplus F) = u_{2k-1}(E) + u_{2k-1}(F)$;
- (ii) $u_{2k-1}(E \otimes F) = rk(E)u_{2k-1}(F) + rk(F)u_{2k-1}(E)$;
- (iii) $u_{2k-1}(E^*) = -u_{2k-1}(E)$. In particular, if E admits an invariant metric, then $u_{2k-1}(E)$ vanish;
- (iv) $u_{2k-1}(E) = 0$ if k is even and E is real.

Combining these invariants u_{2k-1} with the obvious invariant given by the rank of a representation, we obtain a map:

$$U : \text{Rep}_{\mathbb{C}}(\mathfrak{g}) \longrightarrow \mathbb{Z} \times H^{odd}(\mathfrak{g}; \mathbb{R}), \tag{53}$$

and the properties above translate into the fact that U is a morphism of $*$ -semi-rings.

Proof. This is only a closer look at the definition. For instance (iv) means that the restriction map

$$H^*(gl_n(\mathbb{C}), U(n)) \longrightarrow H^*(gl_n(\mathbb{R}), O(n))$$

kills the universal u_{4k-1} (see also [11]). □

Proof of Theorem 6. We now freely use the language of \mathfrak{g} -DG algebras; an exposition can be found e.g. in Chapter 3 of [30]. Let E be a vector bundle over M . Recall (see e.g. [22]) that a \mathfrak{g} -connection on E is a linear map $\Gamma(\mathfrak{g}) \times \Gamma(E) \longrightarrow \Gamma(E)$, $(X, s) \mapsto \nabla_X(s)$, satisfying (10) and (11). It is called flat if $\nabla_{[X,Y]} = [\nabla_X, \nabla_Y]$. Hence a representation of \mathfrak{g} is a vector bundle over M endowed with a flat \mathfrak{g} -connection. Exactly as in the flat case above, we find a 1-1 correspondence between \mathfrak{g} -connection and connection 1-forms $\omega = \omega_{\nabla} \in C^1(\pi^* \mathfrak{g}) \otimes gl_n$ on the gl_n -DG algebra $C^*(\pi^* \mathfrak{g})$. The Chern-Weil construction gives us a characteristic map $k_{\nabla} : W(gl_n) = C^*(gl_n) \otimes S(gl_n^*) \longrightarrow C^*(\pi^* \mathfrak{g})$ defined on the Weil complex of gl_n . Passing to gl_n -basic elements, it induces a map $\text{Inv}(gl_n) \longrightarrow C^*(\mathfrak{g})$ defined

on the algebra of invariant symmetric polynomials on gl_n . The map induced in cohomology $k_\nabla : \text{Inv}(gl_n) \rightarrow H^*(\mathfrak{g})$ will be independent of the connection ∇ . In particular, one can use a \mathfrak{g} -connection which is induced by an usual connection on the vector bundle E , and we see that k_∇ is just the composition of the map $\rho_* : H^*(M) \rightarrow H^*(\mathfrak{g})$ with the usual characteristic map $k_E : \text{Inv}(gl_n) \rightarrow H^*(M)$ of E (and which defines the Chern classes of E). On the other hand, if ∇ is a flat \mathfrak{g} -connection on E , then k_∇ kills the symmetric part of $W(gl_n) = C^*(gl_n) \otimes S(gl_n^*)$, hence the map in cohomology is trivial. \square

Examples 7. When $\mathfrak{g} = TM$ we obtain the usual characteristic classes (and their construction) of flat vector bundle (see e.g. [30]).

When $\mathfrak{g} = \mathcal{F}$ is a foliation of a manifold M , any foliated bundle $E \in \text{Rep}(\mathcal{F})$ defines a vector bundle $E_L = E|_L$ endowed with a flat connection, for each leaf L of \mathcal{F} . Similarly, the foliated cohomology $H^*(\mathcal{F})$ can be viewed as a glueing of the cohomology groups $\{H^*(L)\}_L$, and $u_{2k-1}(E)$ can be viewed as a glueing of the usual characteristic classes $u_{2k-1}(E_L) \in H^{2k-1}(E_L)$ of the flat vector bundles E_L . When applied to the normal bundle $\nu = TM/\mathcal{F}$ of the foliation, we obtain certain characteristic classes $u_{2k-1}(\nu) \in H^{2k-1}(\mathcal{F})$, $1 \leq i \leq q$ where q is the codimension of \mathcal{F} . Note the intimate relation with the secondary characteristic classes found by Bott [4], living in $H^*(M)$. What happens is that the image of those classes in $H^*(\mathcal{F})$ vanish (because the Chern classes vanish), and $u_{2k-1}(\nu)$ are precisely the new relevant classes that live in $H^*(\mathcal{F})$.

Examples 8 (intrinsic characteristic classes). Similar characteristic classes $u_{2k-1}(\mathfrak{g})$, which depend on \mathfrak{g} only (and not on an auxiliary representation) have been defined by R. L. Fernandes [22]. To describe the relation to our classes, we first assume that \mathfrak{g} is regular, i.e. the image \mathcal{F} of the anchor map has constant rank. Let ν be the normal bundle of \mathcal{F} , and let K be the kernel of the anchor map. With the Bott connections (see Examples 4), K and ν are representations of \mathfrak{g} , and one can show [11] that

$$u_{2k-1}(\mathfrak{g}) = u_{2k-1}(K) - u_{2k-1}(\nu).$$

This suggests that Fernandes' $u_{2k-1}(\mathfrak{g})$ can be viewed as the characteristic class of the "formal difference" $K - \nu$. Since there are exact sequences of vector bundles $0 \rightarrow K \rightarrow \mathfrak{g} \rightarrow \mathcal{F} \rightarrow 0$ and $0 \rightarrow \mathcal{F} \rightarrow TM \rightarrow \nu \rightarrow 0$, the previous difference bundle equals to $\mathfrak{g} - TM$ (view these in the K -theory of M). Hence the classes $u_{2k-1}(\mathfrak{g})$ are the new secondary classes which arise from the following vanishing result (implied by Theorem 6):

Lemma 2. *For any regular Lie algebroid \mathfrak{g} over M , one has $Ch(\mathfrak{g} - TM) = 0$ in $H^*(\mathfrak{g})$.*

This can be viewed as an analogue of Bott vanishing theorem [4] for characteristic classes of foliations. Using a nice adaptation of Bott's methods, Fernandes

proves this result (and constructs the resulting secondary classes $u_{2k-1}(\mathfrak{g})$) without any regularity assumption. Although we cannot extend our interpretation of $\mathfrak{g} - TM$ as a representation of \mathfrak{g} from the regular to the non-regular case, this formal difference is always a “representation up to homotopy” of \mathfrak{g} in the sense of [20] (called there “the adjoint representation”). Moreover, we can extend our characteristic classes from representations to representations up to homotopy, and the conclusion is that $u_{2k-1}(\mathfrak{g})$ of [22] are always the characteristic classes of the adjoint representation. For details see [10, 11].

3.3. Relation with the Van Est map

In this subsection we shortly discuss the relation between the characteristic classes previously introduced and the differentiable cohomology: we show that the characteristic map

$$U : \text{Rep}(\mathfrak{g}) \longrightarrow \mathbb{Z} \times H^{\text{odd}}(\mathfrak{g}; \mathbb{R})$$

constructed in the previous section naturally factors, via the Van Est map, through the differentiable cohomology. More precisely, making use both of our Morita invariance and Van Est isomorphism we show:

Theorem 7. *If E is a representation of a Lie groupoid G , and \mathfrak{g} is the Lie algebroid of G , then the characteristic classes $u_{2k-1}(E) \in H^{2k-1}(\mathfrak{g})$ lie in the image of the Van Est map $\Phi : H_d^*(G) \longrightarrow H^*(\mathfrak{g})$.*

Examples 9. The α -simply connected integration of the tangent Lie algebroid TM of a manifold is the fundamental groupoid of M , which is Morita equivalent to the fundamental group $\pi(M)$ of M (cf. Example 2). Hence, by the Morita invariance of differentiable cohomology, we see that our Theorem 7 becomes the well-known result that characteristic classes of flat vector bundles come from the cohomology $H^*(\pi(M))$ of the discrete group $\pi(M)$ (see also Example 7).

Given a foliation (M, \mathcal{F}) , since the normal bundle of \mathcal{F} is endowed with an action of the holonomy groupoid $Hol(M, \mathcal{F})$ (see e.g. [9] for more on representations of the holonomy groupoid), the previous theorem tells us that the classes $u_{2k-1}(\nu)$ (see Example 7) come from $H_d^*(Hol(M, \mathcal{F}))$. In particular, they vanish if the leaf space is an orbifold. More generally, using Proposition 1, we see that if a Lie algebroid admits a proper α -simply connected integration, then all the characteristic classes of its representations must vanish.

Proof of Theorem 7. The idea is quite simple. The frame bundle $P = P(E)$ of an n -dimensional representation E of G is a left G -space and a principal GL_n -bundle, hence can be viewed as a generalized map $\phi_E : G \longrightarrow GL_n$ (and this defines a 1–1 correspondence $\text{Rep}_n(G) \cong \text{Hom}_{\text{gen}}(G, GL_n)$). Hence, by the Morita invariance of

differentiable cohomology (Theorem 1) with trivial coefficients we obtain a map:

$$\phi_E^* : H_d^*(GL_n) \longrightarrow H_d^*(G).$$

On the other hand, by the classical Van Est isomorphism for GL_n , and by the computation of $H^*(gl_n, U(n))$ used also in the previous section, $H_d^*(GL_n)$ is isomorphic to the exterior algebra on generators u_{2k-1} , $1 \leq k \leq n$. What happens is that

$$\phi_E^*(u_{2k-1}) = u_{2k-1}(E). \tag{54}$$

Here are the details. The main problem is to compare the various double complexes which are involved in the definition of our objects. All these double complexes are of Van Est type (below we will fix the notations), with one exception: the double complex arising in the construction of ϕ_E^* . To avoid working with this double complex, we use the following trick. We consider the pull-back π^*G which is a groupoid over P whose space of arrows consists of triples $(p, g, q) \in P \times G^{(1)} \times P$ with $\pi(q) = \beta(g)$, $\pi(p) = \alpha(g)$ (with the first and last projections as target and source map, respectively, and with the obvious composition). For later use, note that its Lie algebroid is precisely $\pi^!\mathfrak{g}$ (see Examples 5). We will make use of the following (true!) morphisms of groupoids

$$G \xleftarrow{f_\pi} \pi^*G \xrightarrow{u_\pi} GL_n. \tag{55}$$

Here f_π is the obvious projection, while u_π associates to an arrow (p, g, q) of π^*G the unique matrix A such that $pA = gq$. The main property of these morphisms is that f_π is an essential equivalence (i.e. defines a Morita equivalence; see 1.1), and, as generalized morphisms, $\phi_E = u_\pi f_\pi^{-1}$.

We now look at the Van Est maps. For any Lie groupoid G , denote by $C(G)$ the double complex appearing in the proof of Theorem 4 (denoted C there); recall that it connects the differentiable and the algebroid cohomology:

$$C_d(G) \xrightarrow{\epsilon} C(G) \xleftarrow{\eta} C(\mathfrak{g}) \tag{56}$$

Moreover, η was a quasi-isomorphism, and the map in cohomology $e\eta^{-1}$ is the Van Est map for G . For $G = GL_n$, both ϵ and η are quasi-isomorphism if one passes to U_n -basic elements in the last two complexes of (56), and this describes the classical Van Est isomorphism for GL_n , $H_d^*(GL_n) \cong H^*(gl_n, U_n)$. Since (56) is natural on G with respect to morphisms of groupoids, by applying it to each of the groupoids in (55), we obtain a commutative diagram

$$\begin{array}{ccccc} C_d^*(G) & \xrightarrow{\sim} & C_d^*(\pi^!G) & \longleftarrow & C_d^*(GL_n) \\ \downarrow & & \downarrow & & \downarrow \epsilon \\ C(G) & \xrightarrow{f_\pi^*} & C(\pi^!G) & \longleftarrow & C(GL_n) \\ \sim \uparrow & & \sim \uparrow & & \sim \uparrow \\ C^*(\mathfrak{g}) & \xrightarrow{f_\pi^*} & C^*(\pi^!\mathfrak{g}) & \xleftarrow{k_E} & C^*(gl_n) \end{array}$$

Maps marked with “ \sim ” are those which are quasi-isomorphisms, and it is not difficult to see that k_E is precisely the map (50) used to construct the characteristic classes of E . By passing to $U(n)$ -basic elements in the complexes which form the small diagram in the bottom right corner, we obtain a similar diagram with the additional property that the maps denoted above by f_π^* and ϵ become quasi-isomorphisms (cf. Theorem 2). Passing to cohomology, and using the previous remarks about the Van Est maps, about the map ϕ_E^* , and about the definition of k_E in (52), we obtain a commutative diagram

$$\begin{array}{ccc}
 H_d^*(G) & \xleftarrow{\phi_E^*} & H_d^*(GL_n) \\
 \Phi \downarrow & & \sim \downarrow \\
 H^*(\mathfrak{g}) & \xleftarrow{k_E} & H^*(\mathfrak{gl}_n, U_n)
 \end{array}$$

which concludes the proof of the theorem. □

4. Applications to Poisson manifolds

In this section we discuss some applications of our results to Poisson manifolds. Although this applications are sort of obvious, our intention is to show the relevance of Lie algebroids and of our results to those interested on Poisson geometry, but less interested on the general theory of Lie groupoids/algebroids. As a resumé: we derive a new proof (and a slight improvement) of the well-known Dazord–Hector integrability criterion for Poisson manifolds [14], we clarify the problem of Morita invariance of Poisson cohomology (known in degree one only [23]), we prove the Morita invariance of the modular class (known under certain conditions only [24]), we explain the nature of the modular class for regular Poisson manifolds, and we argue that the first Poisson cohomology groups and our characteristic classes are obstructions to a representation theory for Poisson manifolds which is analogous to the representation theory for compact Lie groups.

For an introduction to Poisson geometry we recommend [48], as well as [35, 49, 51]. Recall here that a Poisson manifold is a manifold P together with a 2-tensor $\pi \in \Gamma(\Lambda^2 TP)$ with the property that $\{f, g\} = \pi(df, dg)$ defines a Lie bracket on $C^\infty(P)$ satisfying the Leibniz identity $\{f, gh\} = \{f, g\}h + g\{f, h\}$. Call representation of (P, π) any vector bundle E over P together with an external (bilinear) bracket $\{\cdot, \cdot\} : C^\infty(P) \times \Gamma(E) \rightarrow \Gamma(E)$ which satisfies the Leibniz identities $\{fg, s\} = f\{g, s\} + g\{f, s\}$, $\{f, gs\} = \{f, g\}s + g\{f, s\}$, and the Jacobi identity $\{\{f, g\}, s\} = \{f, \{g, s\}\} + \{g, \{f, s\}\}$, for all $f, g \in C^\infty(P)$ and $s \in \Gamma(E)$. Denote by $\text{Rep}(P, \pi)$ the semi-ring of (isomorphism classes of) representations of P .

Recall also that associated to (P, π) there is a Lie algebroid $(T^*P, \rho, [\cdot, \cdot])$, where $\rho : T^*P \rightarrow TP$ is the map induced by π (i.e. $\rho(df)$ is the vector field induced by the derivation $\{f, \cdot\}$), and $[\alpha, \beta] = L_{\rho(\alpha)}\beta - L_{\rho(\beta)}\alpha - d\pi(\alpha, \beta)$. The relevance

here of the Lie algebroid T^*P is that the resulting cohomology is isomorphic to the Poisson cohomology of (P, π) , usually denoted by $H_\pi^*(P)$ (see [50]), while its representations are precisely the representations of (P, π) .

One says that (P, π) is (Hausdorff) integrable if there exists a symplectic (Hausdorff) groupoid over P which induces the given Poisson structure. If G is the α -simply connected integration of (P, π) it follows that $\text{Rep}(P, \pi) \cong \text{Rep}(G)$. For more details, as well as for an exposition of integrability results, we refer to Chapter 9 of [48]. Using the fundamental result of Mackenzie–Xu (Theorem 5.2 in [35] which states that P is integrable if and only if its Lie algebroid is integrable), our Theorem 5 immediately implies the following slight improvement of the Hector–Dazord integrability result [14] for regular Poisson manifolds with totally aspherical symplectic foliation.

Corollary 4. *Let P be a regular Poisson manifold, and let \mathcal{F} be the associated foliation. If:*

- (i) \mathcal{F} has no (non-trivial) vanishing cycles,
- (ii) for any leaf L of \mathcal{F} , $\pi_2(L)$ contains only elements of finite order,

then P is Hausdorff integrable.

Proof. The first condition is equivalent to the Hausdorffness of the monodromy groupoid G of the foliation \mathcal{F} , while the second one is equivalent to the vanishing of the second cohomology groups of its α -fibers (i.e. of the universal covers of the leaves of \mathcal{F}). Since the kernel of the anchor map $\rho : T^*P \rightarrow \mathcal{F} \subset TP$ is always abelian [48], we can apply Theorem 5. \square

Let us now explain how our results clarify the Morita invariance of Poisson cohomology (known to hold in degree one only) in all degrees. Recall [51] that a Morita equivalence between two Poisson manifolds (P_1, π_1) and (P_2, π_2) is a complete full dual pair [49] $P_1 \xleftarrow{\sigma_1} X \xrightarrow{\sigma_2} P_2$ with connected and simply-connected fibers. Morita equivalence only makes sense on the class of integrable Poisson manifolds, and there it does define an equivalence relation (cf. the Remark on pp. 496, and Corollary 3.1 of [51]).

Corollary 5. *Let (P_1, π_1) and (P_2, π_2) be two Poisson manifolds. Any Morita equivalence $P_1 \leftarrow X \rightarrow P_2$ with homologically n -connected fibers induces isomorphisms*

$$H_{\pi_1}^k(P_1) \cong H_{\pi_2}^k(P_2) \tag{57}$$

in all degrees $k \leq n$.

Since Morita equivalent Poisson manifolds have Morita equivalent α -simply connected integrating groupoids (Theorem 3.2 in [51]), whose α -fibers are precisely the fibers of σ_1 and σ_2 , this result immediately follows from our Morita invariance of differentiable cohomology (Theorem 1), and Theorem 4. Alterna-

tively, one remarks that the pull-back groupoids (see Example 5) $\sigma_1^!T^*P_1$ and $\sigma_2^!T^*P_2$ are isomorphic, and invoke Theorem 2. Apart from being much more direct, this last argument also show that Poisson cohomology is invariant under a much weaker notion of Morita equivalence, which does not exclude non-integrable Poisson manifolds (we hope to make this more clear in some other place).

The first part of our Theorem 2 implies that Morita equivalence of Poisson manifolds behaves as it should:

Corollary 6. *Any Morita equivalence $P_1 \longleftarrow X \longrightarrow P_2$ of Poisson manifolds induces isomorphisms*

$$\text{Rep}(P_1, \pi_1) \cong \text{Rep}(P_2, \pi_2) \tag{58}$$

Let me sketch now an argument which explains the nature of the isomorphism between the algebroids $\sigma_1^!T^*P_1$ and $\sigma_2^!T^*P_2$, isomorphism which has been essential to our conclusions. Let $\mathcal{F}(\sigma_1)$ and $\mathcal{F}(\sigma_2)$ be the foliations on X induced by the fibers of σ_1 and σ_2 , respectively. Since $\mathcal{F}(\sigma_2) \cong \pi_1^*T^*P_1$, there is a natural action of $\mathcal{F}(\sigma_2)$ on $\mathcal{F}(\sigma_1)$ (see Example 3), and, similarly, an action of $\mathcal{F}(\sigma_1)$ on $\mathcal{F}(\sigma_2)$. In the terminology of [33], $(\mathcal{F}(\sigma_1), \mathcal{F}(\sigma_2))$ form a matched pair, and we obtain a Lie algebroid structure on $\mathcal{F}(\sigma_1) \oplus \mathcal{F}(\sigma_2)$, which we denote by $\mathcal{F}(\sigma_1) \triangleright \triangleleft \mathcal{F}(\sigma_2)$. It is quite straightforward to see now that this Lie algebroid is isomorphic to our $\sigma_i^!T^*P_i$'s, $i \in \{1, 2\}$. Hence, in the previous two corollaries, the cohomology/representation of our Poisson manifolds are isomorphic also to the cohomology/representation of $\mathcal{F}(\sigma_1) \triangleright \triangleleft \mathcal{F}(\sigma_2)$.

We now turn to the Morita invariance of the modular class of a Poisson manifold, which is known under certain conditions only (cf. section 4 in [24]).

Corollary 7. *Any Morita equivalence $P_1 \longleftarrow X \longrightarrow P_2$ between Poisson manifolds induces an isomorphisms $H_{\pi_1}^1(P_1) \cong H_{\pi_2}^1(P_2)$ which maps the modular class of P_1 into the modular class of P_2 .*

Proof. As mentioned in Examples 6, the modular class of a Poisson manifold P is just the first characteristic class $u_1(L)$ of a canonical one dimensional representation L (denoted Q_A in [20]) of the Lie algebroid T^*P . Let G_1 and G_2 be symplectic integrations of P_1 , and P_2 , respectively, and let $\phi_X : G_1 \cong G_2$ be the Morita equivalence of groupoids induced by X [51]. Then the canonical representations of P_1 and P_2 are related by $L_1 = \phi_X^*L_2$, hence it suffices to use Theorem 7 (more precisely the formula (54) appearing in the proof), and the naturality ensured by Theorem 1. As indicated in the previous discussions, one can also give a direct proof at the infinitesimal (algebroid) level. \square

Clearly, the same argument applies also to the higher characteristic classes. By the constructions of this section we obtain, for any $E \in \text{Rep}(P, \pi)$, certain classes

$u_{2k-1}(E) \in H_\pi^*(P)$, which fit into a homomorphism

$$U : \text{Rep}(P, \pi) \longrightarrow \mathbb{Z} \times H_\pi^{\text{odd}}(P).$$

Corollary 8. *Let $P_1 \longleftarrow X \longrightarrow P_2$ be a Morita equivalence of Poisson manifolds with homologically n -connected fibers, and let $2k - 1 \leq n$. For any two representations E_1, E_2 which correspond to each other in the Morita isomorphism $\text{Rep}(P_1, \pi_1) \cong \text{Rep}(P_2, \pi_2)$, the isomorphism*

$$H_{\pi_1}^{2k-1}(P_1) \xrightarrow{\sim} H_{\pi_2}^{2k-1}(P_2)$$

(cf. Corollary 5) maps $u_{2k-1}(E_1)$ into $u_{2k-1}(E_2)$.

Proof. The Morita invariance of representations follows from the corresponding result for groupoids (see subsection 1.2), and Theorem 3.2 of [51] again. \square

Now, a word about the modular class of regular Poisson manifolds (P, π) . Let \mathcal{F} be the symplectic foliation of P , and let

$$\rho^* : H^*(\mathcal{F}) \longrightarrow H_\pi^*(P) \tag{59}$$

be the map induced in cohomology by the anchor. The following result shows that mild conditions on the geometry of the symplectic foliation (e.g. vanishing of $H^1(\mathcal{F})$) implies the vanishing of the modular class of P . Note the formula (60) in the proof below, which expresses the modular class in terms of our characteristic classes.

Corollary 9. *The modular class of a regular Poisson manifold (P, π) comes from the foliated cohomology of the symplectic foliation \mathcal{F} of π , i.e. is in the image of (59).*

Proof. Denote by \mathfrak{g} the Lie algebroid of P , and let K, ν and \mathcal{F} be as in Examples 7. By the arguments given there, K and ν are representations of \mathfrak{g} . Up to multiplication to a constant, the modular class of P equals to

$$\text{mod}(P) = u_1(K) - u_1(\nu) \in H_\pi^1(P) . \tag{60}$$

Indeed, choosing a linear splitting of the short exact sequences of vector bundles relating $K, \nu, \mathcal{F}, \mathfrak{g}$, and TM , we obtain isomorphisms $TP \cong \mathcal{F} \oplus \nu, \mathfrak{g} \cong K \oplus \mathcal{F}$. The induced isomorphisms $\Lambda^{\text{top}} TP \cong \Lambda^{\text{top}} \mathcal{F} \otimes \Lambda^{\text{top}} \nu$, and $\Lambda^{\text{top}} \mathfrak{g} \cong \Lambda^{\text{top}} K \otimes \Lambda^{\text{top}} \mathcal{F}$ are natural, i.e. do not depend on the choice of the linear splittings. It follows that, as vector bundles, $Q_{\mathfrak{g}} = \Lambda^{\text{top}} K \otimes \Lambda^{\text{top}} \nu^*$. It is not difficult to see that the action of \mathfrak{g} on $Q_{\mathfrak{g}}$ [20] comes from the canonical actions of \mathfrak{g} on K and on ν (mentioned above), hence $u_1(Q_{\mathfrak{g}}) = u_1(K) - u_1(\nu)$. It suffices to remark that K and $\nu \in \text{Rep}(P, \pi)$ are actually representations of \mathcal{F} (of Bott type cf. our Examples 4). \square

The previous argument obviously applies to the higher intrinsic characteristic classes of P as well (but not to those of general representations). Regarding these

classes, we mention here the following immediate consequence (which is known in the case of the modular class)

Corollary 10. *If a representation $E \in \text{Rep}(P, \pi)$ admits a Poisson-invariant metric, then all its characteristic classes vanish.*

The Poisson invariance of a metric h on E is just:

$$\{f, h(s_1, s_2)\} = h(\{f, s_1\}, s_2) + h(s_1, \{f, s_2\}), \quad \forall f \in C^\infty(P), s_1, s_2 \in \Gamma(E).$$

Related to the previous corollary, we mention the following result which shows that the first Poisson cohomology group, together with our characteristic classes are a (serious, we believe) obstruction to a close relation between the geometry of Poisson manifolds and the one of compact Lie groups.

Corollary 11. *If the α -simply connected integration of a Poisson manifold (P, π) is a proper groupoid, then:*

- (i) $H_\pi^1(P) = 0$;
- (ii) *The characteristic classes of any representation $E \in \text{Rep}(P, \pi)$ vanish;*
- (iii) *Any representation of (P, π) admits a Poisson-invariant metric.*

Clearly (i) and (ii) follow from Proposition 1, Theorem 4 (case $n = 1$), and Theorem 7. Note that (ii) also follows from (iii) and from the general properties of characteristic classes mentioned in the previous section. The last part (iii) follows by a classical averaging argument, using a cut-off function as in the proof of Proposition 1.

Note also that (iii) implies, by usual the arguments of the representation theory of compact Lie groups, that any representation can be written as a direct sum of irreducible ones, and rises many questions regarding this analogy.
