## *Short note*     **A remark on the number of automorphisms of finite abelian groups**

---

---

Marius Tărnăuceanu

**Abstract.** Let  $\text{Ab}_0$  be the class of finite abelian groups and consider the function  $f: \text{Ab}_0 \rightarrow (0, \infty)$  given by  $f(G) = |\text{Aut}(G)|/|G|$ , where  $\text{Aut}(G)$  is the automorphism group of a finite abelian group  $G$ . In this short note, we prove that the image of  $f$  is a dense set in  $[0, \infty)$ .

### **1 Introduction**

A well-known question in group theory (see e.g. [5, Problem 12.77]) asks whether it is true that  $|G|$  divides  $|\text{Aut}(G)|$  for every nonabelian finite  $p$ -group  $G$ . This was answered in negative in [3], where for each prime  $p$ , there was constructed a family  $(G_n)_{n \in \mathbb{N}}$  of finite  $p$ -groups such that  $|\text{Aut}(G_n)|/|G_n|$  tends to zero as  $n$  tends to infinity. By considering the function

$$f(G) = \frac{|\text{Aut}(G)|}{|G|}$$

for all finite groups  $G$ , the above result means that zero is an accumulation point of the image of  $f$ . Note that a similar result holds for the function

$$f'(G) = \frac{|\text{Aut}(G)|}{\varphi(|G|)},$$

where  $\varphi$  denotes the Euler totient function (see e.g. [1, 2]). These constitute the starting point for our work.

Our main result shows that all nonnegative real numbers are accumulation points of the image of  $f$ , even if we restrict this function only to abelian groups.

**Theorem 1.1.** *The set*

$$\text{Im}(f) = \{f(G) \mid G \in \text{Ab}_0\}$$

*is dense in  $[0, \infty)$ .*

The proof of Theorem 1.1 follows the same steps as the proofs of [4, Theorem 1.1]. It is based on the next lemma which is a consequence of the proposition outlined on [6, p. 863].

**Lemma 1.2.** *Let  $(x_n)_{n \geq 1}$  be a sequence of positive real numbers such that  $\lim_{n \rightarrow \infty} x_n = 0$  and  $\sum_{n=1}^{\infty} x_n$  is divergent. Then the set containing the sums of all finite subsequences of  $(x_n)_{n \geq 1}$  is dense in  $[0, \infty)$ .*

It also uses the fact that the function  $f$  is multiplicative, that is,

$$f(G_1 \times G_2) = f(G_1)f(G_2)$$

for any finite groups  $G_1, G_2$  of coprime orders.

Finally, we formulate a natural open problem related to the above theorem.

**Open problem.** Is it true that, for every  $a \in [0, \infty) \cap \mathbb{Q}$ , there is a finite (abelian) group  $G$  such that  $f(G) = a$ ?

## 2 Proofs of the main results

First of all, we prove an auxiliary result.

**Lemma 2.1.** *The set  $\text{Im}(f) \cap [0, 1]$  is dense in  $[0, 1]$ .*

*Proof.* Let  $I$  be a finite subset of  $\mathbb{N}$  and let  $p_i$  be the  $i$ th prime number. Since  $f$  is multiplicative, we have

$$f\left(\prod_{i \in I} C_{p_i}\right) = \prod_{i \in I} f(C_{p_i}) = \prod_{i \in I} \frac{p_i - 1}{p_i}$$

and so

$$A = \left\{ \prod_{i \in I} \frac{p_i - 1}{p_i} \mid I \subset \mathbb{N}, |I| < \infty, p_i = i\text{th prime number} \right\} \subseteq \text{Im}(f) \cap [0, 1].$$

Thus it suffices to prove that  $A$  is dense in  $[0, 1]$ .

Consider the sequence  $(x_i)_{i \geq 1} \subset (0, \infty)$ , where  $x_i = \ln\left(\frac{p_i}{p_i - 1}\right)$  for all  $i \geq 1$ . Clearly,  $\lim_{i \rightarrow \infty} x_i = 0$ . We have

$$\lim_{i \rightarrow \infty} \frac{x_i}{\frac{1}{p_i}} = 1.$$

Therefore, since the series  $\sum_{i \geq 1} \frac{1}{p_i}$  is divergent, we deduce that the series  $\sum_{i \geq 1} x_i$  is also divergent. So all hypotheses of Lemma 1.2 are satisfied, implying that

$$\overline{\left\{ \sum_{i \in I} x_i \mid I \subset \mathbb{N}^*, |I| < \infty \right\}} = [0, \infty).$$

This means

$$\overline{\left\{ \ln\left(\prod_{i \in I} \frac{p_i}{p_i - 1}\right) \mid I \subset \mathbb{N}^*, |I| < \infty, p_i = i\text{th prime number} \right\}} = [0, \infty)$$

or equivalently

$$\overline{\left\{ \prod_{i \in I} \frac{p_i}{p_i - 1} \mid I \subset \mathbb{N}^*, |I| < \infty, p_i = i\text{th prime number} \right\}} = [1, \infty).$$

Then

$$\overline{\left\{ \prod_{i \in I} \frac{p_i - 1}{p_i} \mid I \subset \mathbb{N}^*, |I| < \infty, p_i = i\text{th prime number} \right\}} = [0, 1]$$

and consequently

$$\overline{A} = [0, 1],$$

as desired. ■

Note that the conclusion of Lemma 2.1 remains valid if we restrict  $f$  to the class  $\text{Ab}'_0$  of finite abelian groups of odd order, that is,  $\text{Im}(f|_{\text{Ab}'_0}) \cap [0, 1]$  is also dense in  $[0, 1]$ .

We are now able to prove our main result.

*Proof of Theorem 1.1.* We have to prove that, for every  $a \in [0, \infty)$  and every  $\varepsilon > 0$ , there is  $G \in \text{Ab}_0$  such that  $f(G) \in (a - \varepsilon, a + \varepsilon)$ . If  $a \in [0, 1]$ , this follows from Lemma 2.1. Assume now that  $a \in (1, \infty)$ . Since  $\text{Aut}(C_2^n) \cong \text{GL}_n(2)$  has order  $\prod_{k=0}^{n-1} (2^n - 2^k)$ , we have

$$\lim_{n \rightarrow \infty} f(C_2^n) = \lim_{n \rightarrow \infty} \frac{1}{2^n} \prod_{k=0}^{n-1} (2^n - 2^k) = \infty$$

and so we can choose a finite elementary abelian 2-group  $G_1$  such that  $f(G_1) = b > a$ . Then  $\frac{a}{b} \in (0, 1)$ . Let  $\varepsilon_1 = \frac{\varepsilon}{b}$ . By the above remark, there is a finite abelian group of odd order  $G_2$  with  $f(G_2) \in (\frac{a}{b} - \varepsilon_1, \frac{a}{b} + \varepsilon_1)$ . It follows that  $G = G_1 \times G_2 \in \text{Ab}_0$  and

$$f(G) = f(G_1)f(G_2) = bf(G_2) \in (a - \varepsilon, a + \varepsilon).$$

This completes the proof. ■
